Mackenzie, Sir Alexander (c. 1755-1820), Canadian explorer, was probably a native of Inverness. Emigrating to North America at an early age, he was for several years engaged in the fur trade at Fort Chipewyan, at the head of Lake Athabasca, and it was there that his schemes of travel were formed. His first journey, made in 1789, was from Fort Chipewyan along the Great Slave Lake, and down the river which now bears his name to the Arctic Ocean; and his second, made in 1792 and 1793, from Fort Chipewyan across the Rocky Mountains to the Pacific coast near Cape Menzies. He wrote an account of these journeys, Voyages on the River St Lawrence and through the Continent of North America to the Frozen and Pacific Ocean. (London, 1801), which is of considerable interest from the information it contains about the native tribes. It is prefaced by an historical dissertation on the Canadian fur trade. Amassing considerable wealth, Mackenzie was knighted in 1802, and later settled in Scotland. He died at Mulnain, near Dunkeld, on the 11th of March 1820.

Mackenzie, Alexander (1822-1892), Canadian statesman, was born in Perthshire, Scotland, on the 28th of January, 1822. His father was a builder, and young Mackenzie emigrated to Canada in 1842, and worked in Ontario as a stone-mason, setting up for himself later as a builder and contractor at Sarnia with his brother. In 1852 his interest in questions of reform led to his becoming the editor of the Lambton Shield, a local Liberal paper. In 1866 he became a member of the Canadian parliament, where he at once made his mark and was closely connected with the liberal leader, George Brown. He was elected for Lambton to the first Dominion house of commons in 1867, and soon became the leader of the liberal opposition; from 1871 to 1872 he also sat in the Ontario provincial assembly, and held the position of provincial treasurer. In 1873 the attack on Sir John Macdonald's ministry with regard to the Pacific Railway charter resulted in its defeat, and Mackenzie formed a new government, taking the portfolio of public works and becoming the first liberal premier of Canada. He remained in power till 1878, when industrial depression enabled Macdonald to return to office on a protectionist programme. In 1875 Mackenzie paid a visit to Great Britain, and was received at Windsor by Queen Victoria; he was offered a knighthood, but declined it. After his defeat he suffered from failing health, gradually resulting in almost total paralysis, but in 1880 he resigned the leadership of the opposition, he retained a seat in parliament till his death at Toronto on the 17th of April 1892. While perhaps too cautious to be the ideal leader of a young and vigorous community, his grasp of detail, indefatigable industry, and unbending integrity won him the respect even of his political opponents.

His Life and Times by William Buckingham and the Hon. George W. Ross (Toronto, 1862) contains documents of much interest. See also George Stewart, Canada under the Administration of the Earl of Dufferin (Toronto, 1878).

Mackenzie, Sir Alexander Campbell (1847—), British composer, son of an eminent Edinburgh violinist and conductor, was born on the 22nd of August 1847. On the advice of a member of Gungl's band who had taken up his residence in Edinburgh, Mackenzie was sent for his musical education to Sondershausen, where he entered the conservatorium under Ullrich and Stein, remaining there from 1857 to 1861, when he entered the ducal orchestra as a violinist. At this time he made Liszt's acquaintance. On his return home he won the King's Scholarship at the Royal Academy of Music, and remained the usual three years in the institution, after which he established himself as a teacher of the piano, &c., in Edinburgh. He appeared in public as a violinist, taking part in Chappell's quartette concerts, and starting a set of classical concerts. He was appointed preceptor of St George's Church in 1870, and conductor of the Scottish vocal music association in 1873, at the same time getting through a prodigious amount of teaching. He kept in touch with his old friends by playing in the orchestra of the Birmingham Festivals from 1864 to 1873. The most important compositions of this period of Mackenzie's life were the Quartette in E flat for piano and strings, Op. 11, and an
MACKENZIE, SIR GEORGE—MACKENZIE, HENRY

overture, *Carmen*, which owed its first performance to the encouragement and help of von Bölow. On the advice of this great pianist, he gave up his Edinburgh appointments, which he had quite worn him out, and settled in Florence in order to compose. The cantatas *The Bride* (Worcester, 1881) and *Jason* (Bristol, 1882) belong to this time, as well as his first opera. This was commissioned for the Carl Rosa Company, and was written to a version of Merimee’s *Colomba* prepared by Franz Hueffer. It was produced with great success in 1883, and was the first of a too short series of modern English operas; Mackenzie’s second opera, *The Troubadour*, was produced by the same company in 1886; and his third dramatic work was *His Majesty*, an excellent comic opera (Savoy Theatre, 1897). In 1884 his *Rose of Sharon* was given with very great success at the Norwich Festival; in 1885 he was appointed conductor of Novello’s oratorio concerts; *The Story of St Cyprian* came out at the Leeds Festival of 1886; and in 1888 he succeeded Macfarren as principal of the Royal Academy of Music. His overture *Jubal* was produced at Liverpool in 1889, and in London very soon afterwards. A fine setting of the hymn “Veni, Creator Spiritus” was given at Birmingham in 1891, and the oratorio *Bethlehem* in 1894. From 1892 to 1899 he conducted the Philharmonic Concerts, and was knighted in 1894. Besides the works mentioned he has written incidental music to plays, as, for instance, to *Ravenswood, The Little Minister*, and *Coriolanus*; concertos and other works for violin and orchestra, much orchestral music, and many songs and violin pieces. The romantic side of music appeals to Mackenzie far more strongly than any other, and the cases in which he has conformed to the classical conventions are of the rarest. In the orchestral ballad, *La Belle Dame sans Merci*, he touches the note of weird pathos, and in the nautical overture *Britannia* his sense of humour stands revealed. In the two “Scottish Rhapsodies” for orchestra, in the music to *The Little Minister*, and in a beautiful fantasia for pianoforte and orchestra on Scott’s theme, he has seized the essential, not the accidental features of his native music.

MACKENZIE, SIR GEORGE (1636–1691), of Rosehaugh, Scottish lawyer, was the grandson of Kenneth, first Lord Mackenzie of Kintail, and the nephew of Colin and George, first and second earls of Seaforth; his mother was a daughter of Andrew Bruce, principal of St Leonard’s College, St Andrews. He was born at Dundee in 1636, educated at the grammar school there and at Aberdeen, and afterwards at St Andrews, graduating at sixteen. He then engaged for three years in the study of the civil law at Bourges; on his return to Scotland he was called to the bar in 1659, and before the Restoration had risen into considerable practice. Immediately after the Restoration he was appointed a “justice-depute,” and it is recorded that he and his colleagues in that office were ordained by the parliament in 1661 “to repair, once in the week at least, to Musselburgh and Dalkeith, and to try and judge such persons as are there or thereabouts delate of witchcraft.” In the same year he acted as counsel for the marquis of Argyll; soon afterwards he was knighted, and he represented the county of Ross during the four sessions of the parliament which was called in 1669. He succeeded Sir John Nisbet as king’s advocate in August 1677, and in the discharge of this office became implicated in all the worst acts of the Scottish administration of Charles II, earning for himself an unenviable distinction as “the bloody Mackenzie.” His refusal to concur in the measures for dispensing with the penal laws against Catholics led to his removal from office in 1686, but he was reinstated in February 1688. At the Revolution, being a member of convention, he was one of the minority in the division on the forfeiture of the crown. King William was urged to declare him incapacitated for holding any public office, but his refusal to do so cost him his life. The death of Dundee (July 1689) had finally destroyed the hopes of his party in Scotland, Mackenzie betook himself to Oxford, where, admitted a student by a grace passed in 1690, he was allowed to spend the rest of his days in the enjoyment of the ample fortune he had acquired, and in the prosecution of his literary labours. One of his last acts before leaving Edin-
Edinburgh society. He was nicknamed the “man of feeling,” but he was in reality a hard-headed man of affairs with a kindly heart. Some of his literary reminiscences were embodied in his Account of the Life and Writings of John Czermak, 1812. He also wrote a Life of Doctor Blacklock, prefixed to the 1793 edition of the poet’s works. He died on the 14th of January 1831.

In 1807 The Works of Henry Mackenzie were published surreptitiously, and he then himself established the publication of his Works (8 vols., 1808). There is an admiring but discriminating criticism of his work in the Prefatory Memoir prefixed by Sir Walter Scott to an edition of his novels in Ballantyne’s Novelist’s Library (vol. v., 1823).

Mackenzie, Sir John (1838–1901), New Zealand statesman, was born at Ard-Ross, Scotland, in 1838, the son of a crofter. He emigrated to Otago, New Zealand, in 1860. Beginning as a shepherd, he rose to be farm manager at Puketapu near Palmerston South, and then to be a farmer in a substantial way in Shag Valley. In 1865 he was clerk to the local road board and school committee; in 1871 he entered the provincial council of Otago; and on the 11th of December 1881 was elected member of the House of Representatives, in which he sat till 1900. He was also for some years a member of the education board and of the land board of Otago, and always showed a keen interest in a national elementary school system. In the House of Representatives he soon made good his footing, becoming almost at once a recognized spokesman for the smaller sort of rural settlers and a person of influence in the lobbies. He acted as government whip for the coalition ministry of Sir Robert Stout and Sir Julius Vogel, 1884–1887, and, while still a private member, scored his first success as a land reformer by carrying the “Mackenzie clause” in a land act limiting the area which a state tenant might thenceforth obtain on lease. He was still, however, comparatively unknown outside his own province when, in January 1891, his party took office and he aided John Ballance in forming a ministry, in which he himself held the portfolio of lands, immigration and agriculture. From the first he made his hand felt in every matter connected with land settlement and the administration of the vast public estate. Generally his aim was to break up and subdivide the great freehold and leasehold properties which in his time covered four-sevenths of the occupied land of the colony. In his Land Act of 1892 he consolidated and simplified the system of registration, and thereby reduced the burden on dealing with crown lands, and thereafter amended his own act four times. Though owing to a preference for state tenancy over freehold, he never stopped the selling of crown land, and was satisfied to give would-be settlers the option of choosing freehold or leasehold under tempting terms as their form of tenure. As a compromise he introduced the lease in perpetuity or holding for 999 years at a quit rent fixed at 4%; theoretical objections have since led to its abolition, but for fifteen years much genuine settlement took place under its conditions. Broadly, however, Mackenzie’s exceptional success as lands minister was due rather to unfailing determination to stimulate the occupation of the soil by working farmers than to the solution of the problems of agrarian controversy. His best-known experiment was in land repurchase. A voluntary law (1892) was displaced by a compulsory act (1894), under which between £5,000,000 and £6,000,000 had by 1910 been spent in buying and subdividing estates for closer settlers, with excellent results. Mackenzie also founded and expanded an efficient department of agriculture, in the functions of which inspection, grading, teaching and example are successfully combined. It has aided the development of dairying, fruit-growing, poultry-farming, bee-keeping and flax-milling, and done not a little to keep up the standard of New Zealand products. After 1897 Mackenzie had to hold on in the face of failing health. An operation in London in 1899 only postponed the end. He died at his farm on the 6th of August 1901, soon after being called to the legislative council, and receiving a knighthood.

Mackenzie, Sir Morell (1837–1892), British physician, son of Stephen Mackenzie, surgeon (d. 1854), was born at Leytonstone, Essex, on the 7th of July 1837. After going through the course at the London Hospital, and becoming M.R.C.S. in 1858, he studied abroad at Paris, Vienna and Pest; and at Pest he studied under the newly invented laryngoscope under J. N. Czermak. Returning to London in 1862, he worked at the London Hospital, and took his degree in medicine. In 1863 he won the Jacksonian prize at the Royal College of Surgeons for an essay on the “Pathology of the Larynx,” and he then devoted himself to becoming a specialist in diseases of the throat. In 1863 the Throat Hospital in King Street, Golden Square, was founded, largely owing to his initiative, and by his work there and at the London Hospital (where he was one of the physicians from 1866 to 1873) Morell Mackenzie rapidly became recognized throughout Europe as a leading authority, and acquired an extensive practice. So great was his reputation that in May 1887, when the crown prince of Germany (afterwards the emperor Frederick III.) was attacked by the affection of the throat of which he ultimately died, Morell Mackenzie was specially summoned to attend him. The German physicians who had attended the prince since the beginning of March ( Karl Gerhardt, and subsequently Tobold, E. von Bergmann, and others) had diagnosed his ailment on the 18th of May as cancer of the throat; but Morell Mackenzie, after examining the effects of the operation on the larynx and examining the examination by R. Virchow of a portion of the tissue) that the disease was not demonstrably cancerous, that an operation for the extirpation of the larynx (planned for the 21st of May) was unjustifiable, and that the growth might well be a benign one and therefore curable by other treatment. The question was one not only of personal but of political importance, since it was doubted whether any one suffering from an incapacitating disease like cancer could, according to the family law of the Hohenzollerns, occupy the German throne; and there was talk of a renunciation of the succession by the crown prince. It was freely hinted, moreover, that some of the doctors themselves were influenced by political considerations. At any rate, Morell Mackenzie’s opinion was followed: the crown prince went to England, under his treatment, and was present at the Jubilee celebrations in June. Morell Mackenzie was knighted in September 1887 for his services, and decorated with the Grand Cross of the Hohenzollern Order. In November, however, the German doctors were again called into consultation, and it was ultimately admitted that the disease really was cancer; though Mackenzie, with very questionnaire able judgment, more than hinted that it had become malignant since his first examination, in consequence of the irritating effect of the treatment by the German doctors. The crown prince (see Frederick III.) became emperor on the 9th of March 1888, and died on the 15th of June. During all this period a violent quarrel raged between Sir Morell Mackenzie and the German medical world. The German doctors published an account of the illness, to which Mackenzie replied by a work entitled The Fatal Illness of Frederick the Noble (1888), the publication of which caused him to be censured by the Royal College of Surgeons. After this sensational episode in his career, the remainder of Sir Morell Mackenzie’s life was uneventful, and he died somewhat suddenly in London, on the 3rd of February 1892. He published several books on laryngoscopy and diseases of the throat. Mackenzie, William Lyon (1795–1861), Canadian politician, was born near Dundee, Scotland, on the 14th of March 1795. His father died before he was a month old, and the family were left in poverty. After some six years’ work in a shop at Alyth, in April 1820 he emigrated with his mother to Canada. There he became a general merchant, first at York, then at Dundas, and later at Queenston. The discontented condition of Upper Canada drew him into politics, and on the 18th of May 1824 he published at Queenston the first number of the Colonial Advocate, in which the ruling oligarchy was attacked with great asperity. Most of the changes which he advocated were wise and have since been adopted; but the violence of Mackenzie’s attacks roused great anger among the social and political set at York (Toronto), which was headed by John Beverley Robinson. In November
MACKENZIE—MACKEREL

1834 Mackenzie removed to Toronto, but he had little capital; his paper appeared irregularly, and was on the point of suspending publication when his office was attacked and his type thrown into the bay by a number of the supporters of his opponents. In an action against the chief rioters he was awarded $625 and costs, was thus enabled to set up a much larger and more efficient plant, and the Colonial Advocate ran till the 4th of November 1834.

In 1838 he was elected member of parliament for York, but was expelled on the technical ground that he had published in his newspaper the proceedings of the house without authorization. Five times he was expelled and five times re-elected by his constituents, till at last the government refused to issue a writ, and for three years York was without one of its representatives. In May 1832 he visited England, where he was well received by the colonial office. Lastly as the result of his representations, many important reforms were ordered by Lord Goderich, afterwards earl of Ripon, the colonial secretary. While in England, he published Sketches of Canada and the United States, in which, with some exaggeration, many of the Canadian grievances were exposed. On his return in March 1834 he was elected mayor of Toronto. During his year of office, the heroism with which he worked hand in hand with his old enemy, Bishop Strachan, in fighting an attack of cholera, did not prevent him from winning much unpopularity by his officiousness, and in 1835 he was not re-elected either as mayor or alderman. In October 1834 he was elected member of parliament for York, and took his seat in January 1835, the Reformers being now in the majority. A committee on grievances was appointed, as chairman of which Mackenzie presented the admirable Seventh Report on Grievances, largely written by himself, in which the case for the Reformers was presented with force and moderation, and the adoption of responsible government advocated as the remedy.

In the general election of June 1836 the Tory party won a complete victory, Mackenzie and almost all the prominent Reformers being defeated at the polls. This totally unexpected defeat greatly embittered him. On the 4th of July 1836, the anniversary of the adoption of the American Declaration of Independence, he began the publication of the Constitution, which openly advocated a republican form of government. Later in the year he was appointed "agent and corresponding secretary" of the extreme wing of the Reform party, and more and more openly, in his speeches throughout the province, advocated armed revolt. He was also in correspondence with Papineau and the other leaders of the Reformers in Lower Canada, who were already planning a rising. Early in December 1837 Mackenzie gathered a mob of his followers, to the number of several hundred, at Gallows Hill, some miles to the north of Toronto, with the intention of seizing the lieutenant-governor and setting up a provisional government. Misunderstandings among the leaders led to the total failure of the revolt, and Mackenzie was forced to fly to the United States with a price on his head. In the town of Buffalo he collected a disorderly rabble, who seized and fortified Navy Island, in the river between the two countries, and for some weeks troubled the Canadian frontier. After the failure of this attempt he was put to the most pitiful shifts to make a living. In June 1839 he was tried in the United States for a breach of the neutrality laws, and sentenced to eighteen months' imprisonment, of which he served over eleven. While in gaol at Rochester he published the Caroline Almanac, the tone of which may be judged from its references to "Victoria Guelph, the bloody queen of England," and by the title given to the British cabinet of "Victoria Melbourne's bloody divan." He returned to Canada in consequence of the Amnesty Act 1840. A close inspection had cured him of his love for republican institutions.

In 1851 he was elected to parliament for Haldimand, defeating George Brown. He at once allied himself with the Radicals (the "Clear Grits") and, on the leadership of that party being assumed by Brown, became one of his lieutenants. He was still miserably poor, but refused all offers to accept a government position. In 1858 he resigned his seat in the house, owing to incipient softening of the brain, of which he died on the 29th of August 1861.

Turbulent, ungovernable, vain, often the dupe of schemers, Mackenzie united with much that was laughable not a little that was heroic. He could neither be bribed, bullied, nor cajoled. Perhaps the best instance of this is that in 1832 he refused from Lord Goderich an offer of a position which would have given him great influence in Canada and an income of $1,500. He was a born agitator, and as such tended to exaggeration and misrepresentation. But the evils against which he struggled were real and grave; the milder measures of the Constitutional Reformers might have taken long to achieve the results which were due to his hot-headed advocacy.

The Life and Times by his son-in-law, Charles Lindsey (Toronto, 2 vols., 1862), is moderate and fair, though tending to smooth over his anti-British gassonne while in the United States. An abridgment of this work was edited by G. G. S. Lindsey for the "Makers of Canada" series (1909). In The Story of the Upper Canadian Rebellion by J. C. Dent (2 vols., Toronto, 1885), a bitter attack is made on him, which drew a savage reply from another son-in-law, John King, K.C., called The Other Side of the Story. The best short account of his career is given by J. C. Dent in The Canadian Portrait Gallery, vol. ii. (Toronto, 1881).

MACKENZIE, a river of the North-West Territories, Canada, discharging the waters of the Great Slave Lake into the Arctic Ocean. It was discovered and first navigated by Sir Alexander Mackenzie in 1789. It has an average width of 1 m., an average fall of 6 in. to the mile; an approximate discharge, at a medium stage, of 500,000 cub. ft. per second; and a total length, including its great tributary the Peace, of 2,350 m. The latter rises, under the name of the Finlay, in the mountains of British Columbia, and flows north-east and then south-east in the great granite basaltic belt that runs the Rocky Mountains from the west, to its confluence with the Parsnip. From the confluence the waters of the combined rivers, now called the Peace, flow east through the Rocky Mountains, and then north-east to unite with the river which discharges the waters of Lake Athabasca; thence to Great Slave Lake it is known as Slave river. Excluding the rivers which enter these lakes, the principal tributaries of the Peace are: Omineca, Nation, Parsnip, Halfway, North Pine, South Pine, Smoky, Battle, and Loon rivers; those of the Mackenzie are the Liard (650 m. long), which rises near the sources of the Pelly, west of the Rocky Mountains, and breaks through that range on its way to join the parent stream, Great Bear river, which drains Great Bear Lake, Nahanni, Dahadinni, Arctic Red, and Peel rivers. The Mackenzie enters the Arctic Ocean near 135° W. and 65° 50' N., after flowing for 70 to 80 m. through a flat delta, not yet fully surveyed. With its continuation, Slave river, it is navigable from the Arctic Ocean to Fort Smith, a distance of over 1,200 m., and between the latter and the head of Lesser Slave Lake, a further distance of 625 m., there is only one obstruction to navigation, the Grand Rapids near Fort McMurray on the Athabasca river. The Peace is navigable from its junction with Slave river for about 220 m. to Vermilion Falls. The Mackenzie is navigable from about the 10th of June to the 20th of October, and Great Slave Lake from about the 1st of July to the end of October. All the waters and lakes of this great system are abundantly stocked with fish, chiefly white fish and trout, the latter attaining to remarkable size.

MACKEREL, pelagic fishes, belonging to a small family, Scombridae, of which the tunny, bonito, albacore, and a few other tropical genera are members. Although the species are more abundant and number than in most other families of fishes, they are widely spread and extremely abundant, peoples by countless schools the oceans of the tropical and temperate zones, and approaching the coasts only accidentally, occasionally, or periodically.

The mackerel proper (genus Scomber) are readily recognized by their elegantly shaped, well-proportioned body, shining in iridescent colours. Small, thin, deciduous scales equally cover nearly the entire body. There are two dorsal fins, the anterior near the head, composed of 11–14 feeble spines, the second near
the tail with all the rays soft except the first, and behind the second dorsal five or six finlets. The ventral is immediately below the second dorsal, and is also followed by finlets. The caudal fin is crescent-shaped, strengthened at the base by two short ridges on each side. The mouth is wide, armed above and below with a row of very small fixed teeth.

No other fish shows finer proportions in the shape of its body. Every "line" of its build is designed and eminently adapted for rapid progress through the water; the muscles massed along the vertebral column are enormously developed, especially on the back and the sides of the tail, and impart to the body a certain rigidity which interferes with abruptly sideward motions of the fish. Therefore mackerel generally swim in a straightforward direction, deviating sidewardly only when compelled, and rarely turning about in the same spot. They are in almost continuous motion, their power of endurance being equal to the rapidity of their motions. Mackerel, like all fishes of this family, have a firm flesh; that is, the muscles of the several segments are interlaced, and receive a greater supply of blood-vessels and nerves than in other fishes. Therefore the flesh, especially of the larger kinds, is of a red colour; and the energy of their muscular action causes the temperature of their blood to be several degrees higher than in other fishes.

All fishes of the mackerel family are strictly carnivorous; they unceasingly pursue their prey, which consists principally of other fish and pelagic crustaceans. The try of clupeoids, which likewise swim in schools, are followed by the mackerel until they reach some shallow place, which their enemies dare not enter.

Mackerel are found in almost all tropical and temperate seas, with the exception of the Atlantic shores of temperate South America. European mackerel are of two kinds, of which one, the common mackerel, Scomber scombrus, lacks, whilst the other possesses an air-bladder. The best-known species of the latter kind is *S. colias,* the "Spanish" mackerel; the third, *S. pneumotrophus,* is believed by some ichthyologists to be identical with *S. colias.* Be this as it may, we have strong evidence that the Mediterranean is inhabited by other species different from *S. scomber* and *S. colias,* and well characterized by their dentition and coloration. Also the species from St Helena is distinct. Of extra-Atlantic species the mackerel of the Japanese seas are the most nearly allied to the European, those of New Zealand and Australia, and still more those of the Indian Ocean, differing in many conspicuous points. Two of these species occur in the British seas: *S. scomber,* which is the most common there as well as in other parts of the North Atlantic, crossing the ocean to America, where it abounds; and the Spanish mackerel, *S. colias,* which has enormous proportions, but has a different pattern of coloration, the transverse black bands of the common mackerel being in this species narrower, more irregular or partly broken up into spots, whilst the scales of the pectoral region are larger, and the snout is longer and more pointed. The Spanish mackerel is, as the name implies, a native of the seas of southern Europe, but single individuals or small schools frequently reach the shores of Great Britain and of the United States.

The home of the common mackerel (to which the following remarks refer) is the North Atlantic, from the Canary Islands to the Orkneys, and from the Mediterranean and the Black Sea to the coasts of Norway and the United States.

Towards the spring large schools approach the coasts. Two causes have been assigned of this migration: first, the instinct of finding a suitable locality for propagating their species; and, secondly, the search and pursuit of food, which in the warmer season is more abundant in the neighbourhood of land than in the open sea. It is probable that the latter is the chief cause.

In the month of February, or in some years as early as the end of January, the schools first met the entrance of the English Channel, and are met by the more adventurous of the drift-net fishermen many miles west of the Scilly Islands. These early schools, which consist chiefly of one-year and two-year-old fishes, yield much a more variable catch, and would otherwise be the basis of the drift-net fisheries, passing them, for some hitherto unexplained reason, at a greater depth than that to which the nets reach, viz. 20 ft. As the season advances, the schools penetrate farther northwards into St George's Channel or eastwards into the English Channel. The fishery then assumes proportions which render it next in importance to the herring and cod fisheries. In Plymouth alone, some two or three thousand vessels are employed in this fishery. The vessels employed being, though less in number, larger in size than on the English side. The chief centre, however, of the fishery is the Channel of England, where the small fishing boats are outnumbered by hundreds of large boats, both sail and steam, which come chiefly from Lowestoft for the season. Simultaneously with the drift-net the deep-sea-seine and shark-net are also used, and the small local sailing boats, are numbered on the coasts of this country. On the Norwegian coast mackerel fishing does not begin before May, whilst on the English coasts large catches are frequently made in March. Large cargoes are annually imported in ice from Norway to the English market.

After the spawning the schools break up into smaller companies which are much scattered, and offer for two or three months employment to all the hand-line and drift-net fishermen. They now remain on the coasts and return to the open sea. Single individuals or small companies are found, however, on the coast all the year round; they may have become detached from the main bodies, and be seen occasionally for the larger schools which have long left on their return migration.

Although, on the whole, the course and time of the annual migration of mackerel is marked with great regularity, their appearance at certain stations at certain times is subject to Modifications. They may pass a short distance as to evade the nets, and reappear at the surface some days after farther eastwards; they may deviate from their direct line of migration, and even temporarily lose themselves by some means or other. It is certain, however, that at times the mackerel disappeared off Guernsey from the surface, and were accidentally discovered feeding at the bottom. Many were taken at 10 fathoms and deeper with the line, and all were of exceptionally large size, several measuring 18 in, and weighing more than 3 lb.; these are the largest mackerel on record.

The mackerel most esteemed as food is the common species, and individuals from 10 to 12 in. in length are considered the best flavoured. In more southern latitudes, however, this species seems to deteriorate, specimens from the coast of Portugal, and from the Mediterranean and Black Sea, being stated to be dry and resembling in flavour the Spanish mackerel (*S. colias*), which is not esteemed for the table.

**McKim, Charles Follen (1847-1900)**, American architect, was born in Chester county, Pennsylvania, on the 24th of August 1847. His father, James Miller McKim (1819-1874), originally a Presbyterian minister in Pennsylvania, was trained to medicine in the University of Pennsylvania, and was the winner of the prize of the New York University in 1864.

The son studied at Harvard (1866-1867) and at Paris in the École des Beaux-Arts (1867-1870), and in 1872 became an architect in New York City, entering the office of H. H. Richardson; in 1877 he formed a partnership with William Rutherford Mead (b. 1846), the firm becoming in 1879 McKim, Mead & White, when Stanford White (1853-1906) became a partner. McKim was one of the founders of the American Academy in Rome; received a gold medal at the Paris exposition of 1890; in 1903, for his services in the promotion of architecture, received the King's Medal of the Royal Institute of British Architects; and in 1907 became a National Academician. He died at St James, Long Island, N.Y., on the 14th of September 1900. McKim's name is especially associated with the University Club at Yale, the Boston Public Library, the additions to the White House (1906), and, more particularly, with the Boston Public Library, for which the library of St Geneviève in Paris furnished the suggestion.

**Mackinac Island**, a small island in the N.W. extremity of Lake Huron and a part of Mackinac county, Michigan, and a city and summer resort of the same name on the island. The city is on the S.E. shore, at the entrance of the Straits of Mackinac, about 7 m. N.E. of Mackinaw City and 6 m. E.S.E. of St Ignace. Pop. (1890), 665; (1904), 736; (1910), 714. During the summer season, when thousands of people come
here to enjoy the cool and pure air and the island’s beautiful scenery, the city is served by the principal steamboat lines on the Great Lakes and by ferry to Mackinaw city (pop. in 1904, 696), which is served by the Michigan Central, the Grand Rapids & Indiana, and the Duluth, South Shore & Atlantic railroads. The island is about 3 m. long by 2 m. wide. From the remarkably clear water of Lake Huron its shores rise for the most part in tall white limestone cliffs; inland there are strangely shaped rocks and forests of cedar, pine, fir, spruce, juniper, maple, oak, birch, and beech. Throughout the island there are numerous glens, ravines, and caverns, some of which are rich in associations with Indian legends. The city is an antiquated fishing and trading village with modern hotels, club-houses, and summer villas. Fort Mackinac and its grounds are included in a state reservation which embraces about one-half of the island.

The original name of the island was Michilimackinac (“place of the big lame person” or “place of the big wounded person”); the name was apparently derived from an Algonquian tribe, the Mishinimaki or Mishinimaknagog, now extinct. The island was long occupied by Chippewas, the Hurons had a village here for a short time after their expulsion from the East by the Iroquois, and subsequently there was an Ottawa village here. The first white settlement or station was established by the French in 1670 (abandoned in 1701) at Point Saint Ignace on the north side of the strait. In 1761 a fort on the south side (built in 1712) was surrendered to the British. By the treaty of Paris (1783) the right of the United States to this district was acknowledged; but the fort was held by the British until 1796. In July 1812 a British force surprised the garrison, which had not yet learned that war had been declared. In August 1814 an American force under Colonel George Croghan (1791-1834) attempted to recapture the island but was repulsed with considerable loss. By the treaty of Ghent, however, the island was restored, in July 1815, to the United States; Fort Mackinac was maintained by the Federal government until 1855, when it was ceded to the state. From 1830 to 1840 the village was one of the principal stations of the American Fur Company. A Congregational mission was established among the Chippewas on the island in 1827, but was discontinued before 1845. The city of Mackinac Island was chartered in 1899.

MCKINLEY, WILLIAM (1843-1901), twenty-fifth president of the United States, was born in Niles, Trumbull county, Ohio, on the 29th of January 1843. His ancestors on the paternal side were Scotch-Irish who lived at Dervock, Co. Antrim, and spelled the family name “McKinlay.” His great-great-grandfather settled in York county, Pennsylvania, about 1743, and from Chester county, Pennsylvania, his great-grandfather, David McKinley, who served as a private during the War of Independence, moved to Poland where he had grants of 800 to Columbiana county, Ohio. His son William McKinley (b. 1807), like his father an iron manufacturer, was married in 1829 to Nancy Campbell Allison, and to them were born nine children, of whom William, the president, was the seventh. In 1852 the family removed to Poland, Mahoning county, where the younger William was placed at school. At seventeen he entered the junior class of Allegheny College, at Meadville, Pennsylvania; but he studied beyond his strength, and returned to Poland, where for a time he taught in a neighboring country school. When the Civil War broke out in 1861 he promptly enlisted as a private in the 23rd Ohio Volunteer Infantry. He saw service in West Virginia, at South Mountain, where this regiment lost heavily, and at Antietam, where he brought up hot coffee and provisions to the fighting line; for this he was promoted second lieutenant on the 24th of September 1862. McKinley was promoted first lieutenant in February 1864, and for his services at Winchester was promoted captain on the 25th of July 1864. He was on the staff of General George Crook at the battles of Opequon, Fisher Hill, and Cedar Creek in the Shenandoah valley, and on the 14th of March 1865 was brevetted major of volunteers for gallant and meritorious services. He also served on the staff of General Rutherford B. Hayes, who spoke highly of his soldierly qualities. He was mustered out with his regiment on the 26th of July 1865. Four years of army life had changed him from a pale and sickly lad into a man of superb figure and health.

After the war McKinley returned to Poland, and bent all his energy upon the study of law. He completed his preparatory reading at the Albany (N.Y.) law school, and was admitted to the bar at Warren, Ohio, in March 1867. On the advice of an elder sister, who had been for several years a teacher in Canton, Stark county, Ohio, he began his law practice in that place, which was to be his permanent home. He identified himself immediately with the Republican party, campaigned in the Democratic county of Stark in favour of negro suffrage in 1867, and took part in the campaign work on behalf of Grant’s presidential candidacy in 1868. In the following year he was elected prosecuting attorney on the Republican ticket; in 1871 he failed of re-election by 45 votes, and again devoted himself to his profession, while not relaxing his interest in politics.

In 1875 he first became known as an able campaign speaker by his speeches favouring the resumption of specie payments, and in behalf of Rutherford B. Hayes, the Republican candidate for governor of Ohio. In 1876 he was elected by a majority of 3304 to the national House of Representatives. Conditions both in Ohio and in Congress had placed him, and were to keep him for twenty years, in an attitude of aggressive and uncompromising partisanship. His Congressional district was naturally Democratic, and its boundaries were changed two or three times by Democratic legislatures for the purpose of so grouping Democratic strongholds as to cause his defeat. But he overcame what had threatened to be adverse majorities on all occasions from 1876 to 1890, with the single exception of 1882, when, although he received a certificate of election showing that he had been re-elected by a majority of 8, and although he served nearly through the long session of 1883-1884, his seat was contested and taken (May 28, 1884) by his Democratic opponent, Jonathan H. Wallace. McKinley reflected the strong sentiment of his manufacturing constituency in behalf of a high protective tariff, and he soon became known in Congress (where he particularly attracted the attention of James G. Blaine) as one of the most diligent students of industrial policy and question affecting national taxation. In 1878 he took part in the debates over the Wood Tariff Bill, proposing lower import duties; and in the same year he voted for the Blaine-Allison Silver Bill. In December 1880 he was appointed a member of the Ways and Means committee, succeeding General James A. Garfield, who had been elected president in the preceding month, and to whose friendship, particularly in the early days of the Civil War, much is due his earlier years in Congress. He was prominent in the debate which resulted in the defeat of the Democratic Morrison Tariff Bill in 1884, and, as minority leader of the Ways and Means committee, in the defeat of the Mills Bill for the revision of the tariff in 1887-1888. In 1889 he became chairman of the Ways and Means committee and Republican leader in the House of Representatives, after having been defeated by Thomas B. Reed on the third ballot in the Republican caucus for speaker of the House. On the 16th of April 1890 he introduced from the Ways and Means committee the tariff measure known commonly as the McKinley Bill, which passed the House on the 21st of May, passed the Senate (in an amended form, with a reciprocity clause, which McKinley had not been able to get through the House) on the 10th of September, was passed as amended, by the House, and was approved by the president on the 1st of October 1890. The McKinley Bill reduced revenues by its high and in many cases almost prohibitive duties; it
put sugar on the free list with a discriminating duty of 1½
go of one cent a pound on sugar imported from countries giving a
country a bounty for sugar exported, and it gave counties the
in an import substitution policy, it attempted to protect many “infant” industries
such as the manufacture of tin-plate; under its provision for
reciprocal trade agreements (a favourite project of James
G. Blaine, who opposed many of the “protective” features of the Bill) reciprocity treaties were made with Germany, France, Italy, and Belgium, which secured a market in those
countries for American products. Abroad, where the Bill made
McKinley’s name known everywhere, there was bitter opposi-
tion to it and reprisals were threatened by several European
states. In the United States the McKinley Tariff Bill was
one of the main causes of the Democratic victory in the Con-
gressional elections of 1890, in which McKinley himself was
defeated by an extraordinary Democratic gerrymander of his
Congressional district. In November 1890 he was elected
governor of Ohio with a plurality of more than 21,000 votes
in a total of 795,000 votes cast. He was governor of Ohio in
1892-1893, being re-elected in 1893. His administration was
marked by no important events, except that he had on several
occasions in his second term to call out the militia of the state
to preserve order; but it may be considered important because of
the training it gave him in executive as distinguished from
legislative work.

McKinley had been prominent in national politics even
before the passage of the tariff measure bearing his name. In 1888 in the National Republican Convention in Chicago he
was chairman of the committee on resolutions (i.e. the
platform committee) and was leader of the delegation from
Ohio, which had been instructed for John Sherman; after
James G. Blaine withdrew his name there was a movement,
begun by Republican congressmen, to nominate McKinley, who
received 16 votes on the seventh ballot, but passionately
refused to be a candidate, considering that his acquiescence
would be a breach of faith toward Sherman. In 1892 McKinley
was the permanent president of the National Republican
Convention which met in Minneapolis and which renominated
Benjamin Harrison on the first ballot, on which James G.
Blaine received 182 ½ votes, and McKinley, in spite of his
efforts to the contrary, received 182 votes. In 1894 he made
an extended campaign tour before the Congressional elections,
and spoke even in the South. In 1896 he seemed for many
reasons the most “available” candidate of his party for the
presidency: he had no personal enemies in the party; he had
carried the crucial state of Ohio by a large majority in 1893;
his attitude on the coinage question had never been so pro-
neutral as to make him unpopular either with the radical
silver wing or with the conservative “gold-standard” members
of the party. The campaign for his nomination was conducted
with the greatest adroitness by his friend, Marcus A. Hanna,
and in the National Republican Convention held in St Louis
in June he was nominated for the presidency on the first ballot by
661 ½ out of a total of 906 votes. The convention adopted
a tariff plank drafted by McKinley, and, of far greater im-
mediate importance, a plank, which declared that the
Republican party was “opposed to the free coinage of silver,
extcept by international agreement with the leading commercial
countries of the world, which we pledge ourselves to promote,
and until such agreement can be obtained the existing gold
standard must be preserved.” This “gold standard” plank
drove out of the Republican party the Silver Republicans of
the West, headed by Senator Henry M. Teller of Colorado.
The Republican party for the vice-presidency
Garrett A. Hobart of New Jersey. The National Democratic
Convention declared for the immediate opening of the mints
to the free and unlimited coinage of silver at the ratio with
gold of 16 to 1; and it nominated for the presidency William
Jennings Bryan of Nebraska, who also received the nomination of the People’s party and of the National Silver party. There
was a secession from the Democratic party of conservatives
who called themselves the National Democratic party, who
were commonly called Gold Democrats, and who nominated
John M. Palmer (1817-1900) of Illinois for president. In
the re-alignment of 1896 McKinley, who had expected to make the campaign on the issue of a high protective tariff,
was diverted to the defence of the gold standard as the main
issue. While his opponent travelled throughout the country
making speeches, McKinley remained in Canton, where he was
visited by and addressed many Republican delegations.
The campaign was enthusiastic: the Republican candidate
was called the “advance agent of prosperity”; “Bill McKinley
and the McKinley Bill” became a campaign cry; the panic of
1893 was charged to the repeal of the McKinley tariff measure;
and “business men” throughout the states were enlisted
in the cause of “sound money” to support McKinley, who
was elected in November by a popular vote of 7,106,779 to
6,902,925 for Bryan, and by an electoral vote of 271 to 176.

McKinley was inaugurated president of the United States
on the 4th of March 1897. The members of his cabinet were:
secretary of state, John Sherman (whose appointment created
a vacancy in the Senate to which Marcus A. Hanna was elected),
who was succeeded in April 1898 by William R. Day, who in
turn was followed in September 1898 by John Hay; secretary
of the treasury, Lyman J. Gage, a Gold Democrat; secretary of
war, Russell A. Alger, who was succeeded in 1899 by Elihu
Root; secretary of the navy, John D. Long; attorney-general,
Joseph McKenna, succeeded in January 1898 by John William
Griggs; postmaster-general, James A. Gary, succeeded in
April 1898 by Charles Emory Smith; secretary of the interior,
Cornelius N. Bliss, succeeded in February 1899 by Ethan Allen
Hitchcock; and secretary of agriculture, James Wilson. (For
the political history of McKinley’s administration see United
States: History). Immediately after his inauguration the
president summoned Congress to assemble in an extra session on
the 15th of March. The Democratic tariff in 1893 had been
enacted as part of the general revenue system of which
included an income-tax. The income-tax having been declared
unconstitutional by the Supreme Court, the measure had failed
to produce a sufficient revenue, and it had been necessary to
increase the public debt. McKinley’s message to the new
Congress dwelt upon the necessity of an immediate revision of
the tariff and revenue system of the country, and the so-called Dingley Tariff Bill was accordingly passed through
two houses, and was approved by the president on the 24th
of July.

The regular session of Congress which opened in December
was occupied chiefly with the situation in Cuba. President
McKinley showed himself singularly patient and self-controlled
in the midst of the popular excitement against Spain and the
calamity for the people by the United States in behalf of the
Cubans; but finally, on the 23rd of March, he presented an
ultimatum to the Spanish government, and on the 25th
of April, on his recommendation, Congress declared war
upon Spain. During the war itself he devoted himself with great
energy to the mastery of military details; but there was bitter
criticism of the war department resulting in the resignation
of the secretary of war, Russell A. Alger (q.v.). The signing
of a peace protocol on the 12th of August was followed by
the signature at Paris on the 10th of December of articles
of peace between the United States and Spain. After a long
discussion the peace treaty was ratified by the United States
Senate on the 6th of February 1899; and in accordance with
its terms Porto Rico, the Philippine Archipelago, and Guam
were transferred by Spain to the United States, and Cuba
came under American jurisdiction pending the establishment
of an independent republic. Two days before the ratification of the peace treaty, a conflict took place between
armed Filipinos under the leadership of Emilio Aguinaldo
and the American forces that were in possession of Manila.
The six months that had elapsed between the signing of the peace
protocol and the ratification of the treaty had established a
virtual interregnum, Spain’s authority having been practi-
cally destroyed in the Philippines and that of the United States
not having begun. In this period a formidable native Filipino army had been organized and a provisional government created. The war was waged by these Filipinos against the United States, while having for the most part a desultory and guerrilla character, was of a very protracted and troublesome nature. Sovereignty over the Filipinos having been accepted by virtue of the ratification of the Paris treaty, President McKinley was not at liberty to do otherwise than assert the authority of the United States and use every endeavour to suppress the insurrection. But there was bitter protest against this "imperialism," both within the party by such men as Senators George F. Hoar and Eugene Hale, and Thomas B. Reed and Carl Schurz, and, often for purely political reasons, from the leaders of the Democratic party. In the foreign relations of the United States, as directed by President McKinley, the most significant change was the cordial understanding established with the British government, to which much was contributed by his secretary of state, John Hay, appointed to that portfolio when he was ambassador to the court of St. James, and which was due to some extent to the friendliness of the British press and even more markedly of the British navy in the Pacific during the Spanish War. Other important foreign events during McKinley's administration were: the annexation of the Hawaiian Islands (see Hawaii) in August 1898, and the formation of the Territory of Hawaii in April 1900; the cessation in 1899 of the tripartite (German, British, and French) government of the Samoan Islands, and the annexation by the United States of those of the islands east of 171°, including the harbour of Pago-Pago; the participation of American troops in the march of the allies on Pekin in August 1900, and the part played by McKinley's secretary of state, John Hay, in securing a guarantee of the integrity of the Chinese empire. In 1900 McKinley was unanimously renominated by the National Republican Convention which met in Philadelphia on the 16th of June, and which nominated Theodore Roosevelt, governor of New York, for the vice-presidency. The Republican convention demanded the maintenance of the gold standard, and pointed to the fulfilment of some of the most important of the pledges given by the Republican party four years earlier. The intervening period had been one of very exceptional prosperity in the United States, foreign commerce having reached an unprecedented volume, and agriculture and manufactures having made greater advancement than in any previous period of the country's history. The tendency towards the concentration of capital in great industrial combinations, the development of the steel industry, and the establishment of great concerns, had given rise to considerable apprehension; and the Democrats accused President McKinley and the Republican party of having fostered the "trusts." But the campaign against McKinley and the Republican party was not only an "anti-trust" but an "anti-imperialistic." William Jennings Bryan, renominated by the Democratic party in July (and in May by the Fusion People's party) on a free silver platform, declared that imperialism was the "paramount issue" and made a second vigorous campaign; and the opposition to McKinley's re-election, whether based on opposition to his economic or to his foreign policy, was not entirely outside of his own party. As the result of the polling in November, 202 Republican presidential electors were chosen, and 155 Democratic electors, elected in Colorado, Idaho, Montana, Nevada, and the Southern states, represented the final strength of the Bryan and Stevenson ticket. The Republican popular vote was 7,207,923, and the Democratic 6,558,733. Since 1872 no president had been re-elected for a second consecutive term.

In the term of Congress immediately following the presidential election it was found possible to reduce materially the war taxes which had been levied on the outbreak of the Spanish-American War. Arrangements were perfected for the termination of the American military occupation of Cuba and the inauguration of a Cuban Republic as a virtual protectorate of the United States, the American government having arranged with the Cuban constitutional convention for the retention of certain naval stations on the Cuban coast. In the Philippines advanced steps had been taken in the substitution of civil government for military occupation, and a governor-general, Judge William H. Taft, had been appointed and sent to Manila. Prosperity at home was great, and foreign relations were free from complications. The problems which had devolved upon McKinley's administration had been far advanced towards final settlement. He retained without change the cabinet of his first administration. After an arduous and anxious term, the president had reached a period that promised to give him comparative repose and freedom from care. He had secured, through the cooperation of Congress, the permanent reorganization of the army and a very considerable development of the navy. In these circumstances, President McKinley, accompanied by the greater part of his cabinet, set forth in the early summer on a tour to visit the Pacific coast, where he was to witness the launching of the battleship "Ohio" at San Francisco. The route chosen was through the Southern states, where many stops were made, and where the president delivered brief addresses. The heartiness of the welcome accorded him seemed to mark the disappearance of the last vestige of sectional feeling that had survived the Civil War, in which McKinley had participated as a young man. After his return he spent a month in a visit at his old home in Canton, Ohio, and at the end of this visit, by previous arrangement, he visited the city of Buffalo, New York, in order to attend the Pan-American exposition and deliver a public address. This address (Sept. 5, 1901) was a public utterance designed by McKinley to affect American opinion and public policy, and apparently to show that he had modified his views on the tariff. It declared that henceforth the progress of the nations must be through harmony and co-operation, in view of the fast-changing conditions of communication and trade, and it maintained that the time had come for wide-reaching modifications in the tariff policy of the United States, the method preferred by McKinley being that of commercial reciprocity arrangements with various nations. On the following day, the 6th of September 1901, a great reception was held for President McKinley in one of the public buildings of the exposition, all sorts and conditions of men being welcome. Advantage of this opportunity was taken by a young man of Polish parentage, by name Leon Czolgosz, to shoot at the president with a revolver at close range. One of the two bullets fired penetrated the abdomen. After the world had been prepared for news of his death, McKinley was aware of the shot and had an abdominal wound. He died on the 14th. The assassin, who, it was for a time supposed, had been inflamed by the editorials and cartoons of the demagogic opposition press, but who professed to hold the views of that branch of anarchists who believe in the assassination of rulers and persons exercising political authority, was promptly seized, and was convicted and executed in October 1901. McKinley's conduct and utterances in his last days revealed a loftiness of personal character that everywhere elicited admiration and praise. Immediately after his death Vice-President Roosevelt took the oath of office, announcing that it would be his purpose to continue McKinley's policy, while also retaining the cabinet and the principal officers of the government. McKinley's funeral took place at Canton, Ohio, on the 19th of September, the occasion being remarkable for the public manifestations of mourning, not only in the United States, but in Great Britain and other countries; in Canton a memorial tomb has been erected.

Though he had not the personal magnetism of James G. Blaine, whom he succeeded as a leader of the Republican party and whose views of reciprocity he formally adopted in his last public address, McKinley had great personal suavity and dignity, and was thoroughly well liked by his party colleagues. As a politician he was always more the people's representative than their leader, and that he "kept his ear to the ground" was the source of much of his power and at the same time was his greatest weakness: his address at Buffalo the day before his assassination seems to voice his appreciation of the change
in popular sentiment regarding the tariff laws of the United States and is the more remarkable as coming from the foremost champion for years of a form of tariff legislation devised to stifle international competition. His apparently inconsistent record on the coinage question becomes consistent if considered in the same way, as the expression of the gradually changing views of his constituency. And it may not be fanciful to suggest that the obvious growth of McKinley in breadth and power during his term as president was due to his being the representative of a larger constituency, less local and less narrow-minded. He was an able but far from brilliant campaign speaker. His greatest administrative gift was a fine intuition in choosing men to serve him. McKinley's private life was irreproachable; and very fine was his devotion to his wife, Ida Saxton (d. 1907), whom he had married in Canton in 1871, who was throughout his political career a confirmed invalid. He was from his early manhood a prominent member of the Methodist Episcopal Church.

His Speeches and Addresses were printed in two volumes (New York, 1893 and 1901).

MCKINNEY, a city and the county-seat of Collin county, Texas, U.S.A., about 30 m. N. by E. of Dallas. Pop. (1890), 2358; (1900), 4342 (917 negroes); (1010) 4714. It is served by the Missouri, Kansas & Texas and the Houston & Texas Central railways, and by the Dalles & Sherman inter-urban (electric) line, the central water power of which is immediately north of the city. McKinney is in a fine farming region; there are also manufactures. The municipal water supply is obtained from artesian wells. The first settlement in Collin county was made about 10 m. north of what is now McKinney in 1841. McKinney was named, as was the county, in honour of Collin McKinney, a pioneer in the region and a signer of the Declaration of the Independence of Texas. It was settled in 1844, was laid out and became the county-seat in 1846, and was first chartered as a city in 1874.

MACKINTOSH, SIR JAMES (1765-1832), Scottish publicist, was born at Aldourie, 7 m. from Inverness, on the 24th of October 1765. He came of old Highland families on both sides. He went in 1780 to college at Aberdeen, where he made a friend of Robert Hall, afterwards the famous preacher. In 1784 he proceeded for the study of medicine to Edinburgh, where he participated to the full in the intellectual ferment, but did not quite neglect his medical studies, and took his degree in 1787.

In 1788 Mackintosh removed to London, then agitated by the trial of Warren Hastings and the king's first lapse into insanity. He was much more interested in these and other political events than in his professional prospects; and his attention was specially directed to the events and tendencies which caused or preceded the Revolution in France. In 1789 he married his first wife, Catherine Stuart, whose brother Daniel afterwards became editor of the Morning Post. His wife's prudence was a corrective to his own unpractical temperament, and his efforts in journalism became fairly profitable. Mackintosh was soon absorbed in the question of the time; and in April 1791, after long meditation, he published his Vindiciae Gallicae. A reply to Burke's Reflections on the French Revolution. It was the only worthy answer to Burke that appeared. It placed the author in the front rank of European publicists, and won him the friendship of some of the most distinguished men of the time, including Burke himself. The success of the Vindiciae finally decided him to give up the medical for the legal profession. He was called to the bar in 1795, and gained a considerable reputation there as well as a tolerable practice. In 1797 his wife died, and next year he married Catherine Allen, sister-in-law of Josiah and John Wedgwood, through whom he introduced Coleridge to the Morning Post. As a lawyer his greatest public efforts were his lectures (1799) at Lincoln's Inn on the law of nature and nations, of which the introductory discourse was published, and his eloquent defence (1803) of Jean Gabriel Peltier, a French refugee, tried at the instance of the French government for a libel against the first consul. In 1803 he was knighted, and received the post of recorder at Bombay. The spott child of London society was not at home in India, and he was glad to return to England, where he arrived in 1812.

He courteously declined the offer of Perceval to resume political life under the auspices of the dominant Tory party, though tempting prospects of office in connexion with India were opened up. He entered parliament in the Whig interest as member for Nairn. He sat for that county, and afterwards for Knaresborough, till his death. In London society, and in Paris during his occasional visits, he was a recognized favourite for his genial wisdom and his great conversational power. On Mme de Stael's visit to London he was the only Englishman capable of representing his country in talk with her. His parliamentary career was marked by the same wide and candid liberalism as his private life. He opposed the reactionary measures of the Tory government, supported and afterwards succeeded Romilly in his efforts for reforming the criminal code, and took a leading part both in Catholic emancipation and in the Reform Bill. But he was too little of a partisan, too warm by sympathy and candid, as well as too esunate, to be a telling speaker in parliament, and was consequently surpassed by more practical men whose powers were incomparably inferior. From 1818 to 1824 he was professor of law and general politics in the East India Company's College at Haileybury.

In the midst of the attractions of London society and of his parliamentary avocations Mackintosh felt that the real work of his life was being neglected. His great ambition was to write a history of England. His studies both in English and foreign speculation led him to cherish the design also of making some worthy contribution to philosophy. It was not till 1828 that he set about the first task of his literary ambition. This was the Dissertation on the Progress of Ethical Philosophy, pre-fixed to the seventh edition of the Encyclopaedia Britannica. The dissertation, written mostly in ill-health and in snatches of time taken from his parliamentary engagements, was published in 1831. It was severely attacked in 1835 by James Mill in his Fragment on Mackintosh. About the same time he wrote for the Cabinet Cyclopaedia a "History of England from the Earliest Times to the Final Establishment of the Reformation." His more elaborate History of the Revolution, for which he had made great researches and collections, was not published till after his death. Already a privy councillor, Mackintosh was appointed commissioner for the affairs of India under the Whig administration of 1830. He died on the 30th of May 1832.

Mackintosh was undoubtedly one of the most cultured and catholic-minded men of his time. His studies and sympathies embraced almost every human interest, except pure science. But the width of his intellectual sympathies, joined to a constitutional indecision and vis inertiae, prevented him from doing more enduring work. Vindiciae Gallicae was the verdict of a philosophic Liberal on the development of the French Revolution up to the spring of 1791, and though the excesses of the revolutionists compelled him a few years after to express his entire agreement with the opinions of Burke, his defence of the "rights of man" is a valuable statement of the cultured Whig's point of view at the time. The History of the Revolution in England, breaking off at the point where William of Orange is preparing to intervene in the affairs of England, is chiefly interesting because of Macaulay's admiring essay on it and its author.

A Life, by his son R. J. Mackintosh, was published in 1836.

MACKLIN, CHARLES (c. 1699-1797), Irish actor and playwright, whose real name was McLaughlin, was born in Ireland, and had an adventurous youth before coming to Bristol, where he made his first appearance on the stage as Richmond in Richard III. He was at Lincoln's Inn Fields about 1725, and by 1733 was at Drury Lane, where the quarrel between the manager and the principal actors resulted in his getting better parts. When the trouble was over and these were taken from
him, he went to the Haymarket, but he returned in 1734 to Drury Lane and acted there almost continuously until 1748. Then for two seasons he and his wife (d. c. 1728), an excellent actress, were in Dublin under Sheridan, then back in London at Covent Garden. He played a great number of characters, principally in comedy, although Shylock was his greatest part, and Iago and the Ghost in Hamlet were in his repertory. At the end of 1753 Macklin bade farewell to the stage to open a tavern, near the theatre, where he personally supervised the serving of dinner. He also delivered an evening lecture, followed by a debate, which was soon a hopeless subject of ridicule. The tavern failed, and Macklin returned to the stage, and played for a number of years in London and Dublin. His quick temper got him into constant trouble. In a foolish quarrel over a wig in 1735 he killed a fellow actor in the green-room at Drury Lane, and he was constantly at law over his various contracts and quarrels. The bitterest of these arose on account of his appearing as Macbeth at Covent Garden in 1772. The part was usually played there by William Smith, and the public would not brook a change. A few nights later the audience refused to hear Macklin as Shylock, and shouted that he should be removed from the stage; Macklin demanded his discharge. This was done in order to quell the riot. His lawsuit, well conducted by himself, against the leaders of the disturbance resulted in an award of £600 and costs, but Macklin magnanimously elected instead that the defendants should take £100 in tickets at three benefits for himself, his daughter and the management. He returned to Covent Garden, but his appearances thereafter were less frequent, ending in 1789, when as Shylock, at his benefit, he was only able to begin the play, apologize for his wandering memory, and retire. He lived until the 11th of July 1797, and his last years were provided for by a subscription edition of two of his best plays, The Man of the World and Love in a Maze. Macklin’s daughter, Mary Macklin (c. 1734-1781), was a well-known actress in her day.

See Edward A. Parry, Charles Macklin (1901).

**MACK VON LEIBERICH, KARL, FREIHERR (1732-1828),** Austrian soldier, was born at Nennlingen, in Bavaria, on the 25th of August 1732. In 1770 he joined an Austrian cavalry regiment, in which his uncle, Leiberich, was a squadron commander, becoming an officer seven years later. During the brief war of the Bavarian Succession he was selected for service on the staff of Count Kinsky, under whom, and subsequently under the commander-in-chief Field Marshal Count Lacy, he did excellent work. He was promoted first lieutenant in 1778, and captain on the quartermaster-general’s staff in 1783. Count Lacy, then the foremost soldier of the Austrian army, had the highest opinion of his young assistant. In 1785 Mack married Katherine Gabrieul, and was enrolled under the name of Mack von Leiberich. In the Turkish war he was employed on the headquarters staff, becoming in 1788 major and personal aide-de-camp to the emperor, and in 1789 lieutenant-colonel. He distinguished himself greatly in the storming of Belgrade. Shortly after this, disagreements between Mack and Louden, now commander-in-chief, led to the former’s demanding a court-martial and leaving the front. He was, however, given a colony (1789) and the order of Maria Theresa, and in 1791 Louden and Mack, having been reconciled, were again on the field together. During these campaigns Mack received a severe injury to his head, from which he never fully recovered. In 1793 he was made quartermaster-general (chief of staff) to Prince Josias of Saxe-Coburg, commanding in the Netherlands; and he enhanced his reputation by the ensuing campaign. The young Archduke Charles, who won his own first laurels in the action of the 1st of March 1793, wrote after the battle, “Above all we have to thank Colonel Mack for these successes.” Mack distinguished himself again on the field of Neerwinden; and he had a leading part in the negotiations between Coburg and Dumouriez. He continued to serve as quartermaster-general, and was now made titular chief (Inhaber) of a cuirassier regiment. He received a wound at Famars, but in 1794 was once more engaged, having at last been made a major-general. But the failure of the allies, due though it was to political and military factors and ideas, over which Mack had no control, was ascribed to him, as their successes of March–April 1793 had been, and he fell into disfavour in consequence. In 1797 he was promoted lieutenant field marshal, and in the following year he accepted, at the personal request of the emperor, the command of the Neapolitan army. But with the unpromising material of his new command he could do nothing against the French revolutionary troops, and before long, being in actual danger of being murdered by his men, he took refuge in the French camp. He was promised a free pass to his own country, but Napoleon ordered that he should be sent to France as a prisoner of war. Two years later he escaped from Paris in disguise. The allegation that he broke his parole is false. He was not employed for some years, but in 1804, when the war party in the Austrian court needed a general to oppose the peace policy of the Archduke Charles, Mack was made quartermaster-general of the army, with instructions to prepare for a war with France. He did all that was possible within the available time to reform the army, and on the opening of the war of 1805 he was made quartermaster-general. When the Archduke Ferdinand commanded the army which opposed Napoleon in Bavaria, but his position was ill-defined and his authority treated with slight respect by the other general officers. For the events of the Ulm campaign and an estimate of Mack’s responsibility for the disaster, see NAPOLeONIC CAMPAIGNS. After Austerlitz, Mack was tried by a court-martial, sitting from February 1806 to June 1807, and sentenced to be deprived of his rank, his regiment, and the order of Maria Theresa, and to be imprisoned for two years. He was released in 1808, and in 1819, when the ultimate victory of the allies had obliterated the memory of earlier disasters, he was, at the request of Prince Schwarzenberg, reinstated in the army as lieutenant field marshal and a member of the order of Maria Theresa. He died on the 22nd of October 1828 at S. Fülten.

**McLANE, LOUIS** (1786–1837), American political leader, was born in Smyrna, Delaware, on the 28th of May 1786, son of Allan McLane (1746–1829), a well-known Revolutionary soldier. He was admitted to the bar in 1807. He entered politics as a Democrat, and served in the Federal House of Representatives in 1817–1827 and in the Senate in 1827–1829. He was minister to England in 1829–1831, and secretary of the treasury in Jackson’s cabinet from 1831 (when in his annual report he argued for the United States Bank) until May 1833, when he was transferred to the state department. He retired from the cabinet in June 1834. He was president of the Baltimore & Ohio railway in 1837–1847, minister to England in 1843–1846, and delegate to the Maryland constitutional convention of 1850–1851. He died in Baltimore, Maryland, on the 7th of October 1852.

**McLane, Robert Milligan McLane (1815-1868)** graduated at West Point in 1837, resigned from the army in 1843, and practised law in Baltimore. He was a Democratic representative in Congress in 1843–1851 and again in 1879–1883, governor of Maryland in 1864–1865, U.S. commissioner to China in 1833–1851, and minister to Mexico in 1859–1860 and to France in 1868–1869.

See R. M. McLane’s Reminiscences, 1827–1897 (privately printed, 1897).

**MACLAREN, CHARLES** (1782–1856), Scottish editor, was born at Ormiston, Haddingtonshire, on the 7th of October 1782, the son of a farmer and cattle-dealer. He was almost entirely self-educated, and when a young man became a clerk in Edinburgh. In 1817, with others, he established the Scotsman newspaper in Edinburgh and at first acted as its editor. Offered as a post as clerk in the custom house, he resigned his editorial...
position, resuming it in 1820, and resigning it again in 1845. In 1830 Maclaren was made editor of the sixth edition of the *Encyclopaedia Britannica*. From 1864-1866 he was president of the Geological Society of Edinburgh, in which city he died on the 10th of September 1866.

**MACLAIREN, IAN, the pseudonym of JOHN WATSON (1850–1907), Scottish author and divine.** The son of John Watson, a civil servant, he was born at Manningtree, Essex, on the 3rd of November 1850, and was educated at Stirling and at Edinburgh University, afterwards studying theology at New College, Edinburgh, and at Tübingen. In 1874 he entered the ministry of the Free Church of Scotland and became assistant minister of Barclay Church, Edinburgh. Subsequently he was minister at Loglealmoad in Perthshire and at Glasgow, and in 1880 he became minister of Sefton Park Presbyterian church, Liverpool, from which he retired in 1905. In 1886 he was Lyman Beecher lecturer at Yale University, and in 1900 he was moderator of the synod of the English Presbyterian church. While travelling in America he died at Mount Pleasant, Iowa, on the 6th of May 1907. Ian Maclaren's first sketches of rural Scottish life, *Beside the Bonnie Brier Bush* (1894), achieved extraordinary popularity and were followed by other successful books, *The Days of Auld Lang Syne* (1895), *Kate Carnegie and those Ministers* (1896) and *Afterwards and other Stories* (1898). Under his own name Watson published several volumes of sermons, among them *The Upper Room* (1895); *The Mind of the Master* (1896) and *The Potter's Wheel* (1897).

**MACLaurin, colin (1698-1746), Scottish mathematician, was the son of a clergyman, and born at Kilmodan, Argyllshire.** In 1706 he entered the university of Glasgow, where he exhibited a decided genius for mathematics, more especially for geometry; it is said that before the end of his sixteenth year he had discovered many of the theorems afterwards published in his *Geometria organica*. In 1717 he was elected professor of mathematics in Marischal College, Aberdeen, as the result of a competitive examination. Two years later he was admitted F.R.S., and made the acquaintance of Sir Isaac Newton. In 1719 he published his *Geometria organica, sive descriptio linearum curvarum universalis*. In it Maclaurin developed several theorems due to Newton, and introduced the method of generating conics which bears his name, and showed that many curves of the third and fourth degrees can be described by the intersection of two movable angles. In 1721 he wrote a supplement to the *Geometria organica*, which he afterwards published, with extensions, in the *Philosophical Transactions* for 1735. This paper is principally based on the following letter to him, which is an extended sentence of Pascal's hexagram: "If a polygon move so that each of its sides passes through a fixed point, and if all its summits except one describe curves of the degrees m, n, p, &c, respectively, then the free summit moves on a curve of the degree mn... which reduces to mpi... when the fixed points all lie on a right line." In 1722 Maclaurin travelled as tutor and companion to the eldest son of Lord Polwarth, and after a short stay in Paris resided for some time in Lorraine, where he wrote an essay on the percussion of bodies, which obtained the prize of the French Academy of Sciences for the year 1724. The following year he was elected professor of mathematics in the university of Edinburgh on the urgent recommendation of Newton. After the death of Newton, in 1728, his nephew, John Conduit, applied to Maclaurin for his assistance in publishing an account of Newton's life and discoveries. This Maclaurin gladly undertook, but the death of Conduit put a stop to the project. In 1740 Maclaurin divided with Leonhard Euler and Daniel Bernoulli the prize offered by the French Academy of Sciences for an essay on tides. His *Treatise on Fluids* was published at Edinburgh in 1742, in two volumes. In the preface he states that the work was undertaken in consequence of the attack on the method of fluxions made by George Berkeley in 1734. Maclaurin's object was to found the doctrine of fluxions on geometrical demonstration, and thus to answer all objections to his method as being founded on false reasoning and full of mystery. The most valuable part of the work is that devoted to physical applications, in which he embodied his essay on the tides. In this he showed that a homogeneous fluid mass revolving uniformly round an axis under the action of gravity ought to assume the form of an ellipsoid of revolution. The importance of this investigation in connexion with the theory of the tides, the figure of the earth, and other kindred questions, has always caused it to be regarded as one of the great problems of mathematical physics. Maclaurin was the first to introduce into mechanics, in this discussion, the important conception of surfaces of level; namely, surfaces at each of whose points the total force acts in the normal direction. He also gave in his *Fluxions*, for the first time, the correct theory for distinguishing between maxima and minima in general, and pointed out the importance of the distinction in the theory of the multiple points of curves. In 1745, when the rebels were marching on Edinburgh, Maclaurin took a most prominent part in preparing trenches and barricades for its defence. The anxiety, fatigue and cold to which he was thus exposed, affecting a constitution naturally weak, laid the foundation of the disease to which he afterwards succumbed. As soon as the rebel army got possession of Edinburgh Maclaurin fled to England, to avoid making submission to the Pretender. He accepted the invitation of T. Herring, then archbishop of York, with whom he remained until it was safe to return to Edinburgh. He died of dropsy on the 14th of June 1746, at Edinburgh. Maclaurin was married in 1733 to Anne, daughter of Walter Stewart, solicitor-general for Scotland. His eldest son John, born in 1734, was distinguished as an advocate, and appointed one of the judges of the Scottish court of session, with the title of Lord Darghorne. He inherited an attachment to scientific discovery, and was one of the founders of the Royal Society of Edinburgh, in 1782.

After Maclaurin's death his account of Newton's philosophical discoveries was published by Patrick Murdoch, and also his algebra in 1748. As an appendix to the latter he expressed his *De linearium geometricarum proprietatibus generalibus tractatus*, a treatise of remarkable elegance. Of the more immediate successors of Newton in Great Britain Maclaurin is probably the only one who can be placed in competition with the great mathematicians of the continent of Europe at the time. (B. W.)

**M'lenNan, john ferguson (1827–1881),** Scottish ethnologist, was born at Inverness on the 14th of October 1827. He studied at King's College, Aberdeen, where he graduated with distinction in 1849, then proceeding to Cambridge, where he remained till 1855 without taking a degree. He was called to the Scottish bar in 1857, and in 1871 was appointed parliamentary draughtsman for Scotland. In 1865 he published *Primitiva Marriage*, in which, arguing from the prevailing of the symbolical form of capture in the marriage ceremonies of primitive races, he developed an intelligible picture of the growth of the marriage relation and of systems of kinship (see Family) according to natural laws. In 1866 he wrote in the *Fortnightly Review* (April and May) an essay on "Kinship in Ancient Greece," in which he proposed to test by early Greek facts the theory of the history of kinship set forth in *Primitiva Marriage*; and three years later appeared a series of essays on "Totemism" in the same periodical for 1869–1870 (the germ of which had been contained in the paper just named), which mark the second great step in his systematic study of early society. A reprint of *Primitiva Marriage*, with "Kinship in Ancient Greece" and some other essays not previously published, appeared in 1876, under the title of *Primitiva Marriage: An Essay on Kinship in Ancient Greece and Other Subjects*. The new essays in this volume were mostly critical, but one of them, in which perhaps his guessing talent is seen at its best, "The Divisions of the Irish Family," is an elaborate discussion of a problem which has long puzzled both Celtic scholars and jurists; and in another, "On the Classificatory System of Relationship," he propounded a new explanation of a series of facts which, he thought, might throw light upon the early history of society, at the same time putting to the test of those facts the theories he had set forth in *Primitiva Marriage*. Papers
Macleod, Henry Dunning (1821-1902), Scottish economist, was born in Edinburgh, and educated at Eton, Edinburgh University, and Trinity College, Cambridge, where he graduated in 1843. He travelled in Europe, and in 1849 was called to the English bar. He was employed in Scotland on the work of poor-law reform, and devoted himself to the study of economics. In 1856 he published his Theory and Practice of Bankruptcy, in 1858 Elements of Political Economy, and in 1859 A Dictionary of Political Economy. In 1873 appeared his Principles of Economist Philosophy, and other books on economics and banking were published later. Between 1868 and 1870 he was employed by the government in digesting and codifying the law of bills of exchange. He died on the 16th of July 1905.

Macleod's principal contribution to the study of economics consists in his strict construction of the theory of credit, to which he was the first to give due prominence. For a judicious discussion of the value of Macleod's writings, see an article on "The Revolt against Orthodox Economics" in the Quarterly Review for October 1901 (No. 388).

Macleod, Norman (1812-1872), Scottish divine, son of Rev. Norman Macleod (1783-1862), and grandson of Rev. Norman Macleod, minister of Morven, Argyllshire, was born at Campbeltown on the 3rd of June 1812. In 1827 he became a student at Glasgow University, and in 1831 went to Edinburgh to study divinity under Dr Thomas Chalmers. On the 18th of March 1838 he became parish minister at Loudoun, Ayrshire. At this time the troubles in the Scottish Church were already gathering to a head (see Free Church of Scotland). Macleod, although he had no love for lay patronage, and wished the Church to be free to do its proper work, clung firmly to the idea of a national Established Church, and therefore remained in the Establishment when the disruption took place. He was one of those who took a moderate course in the non-intrusion controversy, holding that the fitness of those who were presented to parishes should be judged by the presbyteries—the principle of Lord Aberdeen's Bill. On the secession of 1843 he was offered many different parishes, and having finally settled at Dalkeith, devoted himself to parish work and to questions affecting the Church as a whole. He was largely instrumental in the work of strengthening the Church. In 1847 he became one of the founders of the Evangelical Alliance, and from 1849 edited the Christian Instructor (Edinburgh). In 1851 he was called to the Barony church, Glasgow, in which city the rest of his days were passed. There the more liberal theology rapidly made way among a people who judged it more by its fruits than its arguments, and Macleod won many adherents by his practical schemes for the social improvement of the people. He instituted temperance refreshment rooms, a congregational penny savings bank, and held services specially for the poor. In 1866 Macleod was appointed editor of the new monthly magazine Good Words, which was mainly of a religious character, became widely popular. His own literary work, nearly all of which originally appeared in its pages—sermons, stories, travels, poems—was only a by-product of a busy life. By far his best work was the spontaneous and delightful Reminiscences of a Highland Parish (1867). While Good Words made his name known, and helped the cause he had so deeply at heart, his relations with the queen and the royal family strengthened yet further his position in the country. Never since Principal Carstairs had any Scottish clergyman been on such terms with his sovereign. In 1865 he risked an encounter with Scottish Sabbatarian ideas. The presbytery of Glasgow issued a pastoral letter on the subject of Sunday trains and other infringements of the Sabbath. Macleod protested against the grounds on which its stenches were based. For a time, owing partly to a misleading report of his statement, he became "the man in all Scotland most profoundly distrusted." But four years later the Church accorded him the highest honour in her power by choosing him as moderator of her general assembly. In 1867, along with Dr Archibald Watson, he was sent to India, to inquire into the state of the missions. He undertook the journey in spite of failing health, and seems never to have recovered from its effects. He returned resolved to devote the rest of his days to rousing the Church to her duty in the sphere of foreign missions, but his health was now broken, and his old energy flagged. He died on the 16th of June 1872, and was buried at Campsie. He was one of the greatest of Scottish religious leaders, a man of wide sympathy and high ideals. His Glasgow church was named after him the "Macleod Parish Church," and the "Macleod Missionary Institute" was erected by the Barony church in Glasgow. Queen Victoria gave two memorial windows to Crathie church as a testimony of her admiration for his work.

See Memoir of Norman Macleod, by his brother, Donald Macleod (1874).

Macleise, Daniel (1806-1872), Irish painter, was born at Cork, the son of a Highland soldier. His education was the plainest kind, but he was eager for culture, fond of reading, and anxious to become an artist. His father, however, placed him, in 1820, in Newenham's Bank, where he remained for two years, and then left to study in the Cork school of art. In 1825 it happened that Sir Walter Scott was travelling in Ireland, and young Macleise, having seen him in a book-seller's shop, made a surreptitious sketch of the great man, which he afterwards lithographed. It was exceedingly popular, and the artist became celebrated enough to receive many commissions for portraits, which he executed, in pencil, with very careful treatment of detail and accessory. Various influential friends perceived the genius and promise of the lad, and were anxious to furnish him with the means of studying in the metropolis; but with rare independence he refused all aid, and by careful economy saved a sufficient sum to enable him to leave for London. There he made a lucky hit by a sketch of the younger Kean, which, like his portrait of Scott, was lithographed and published. He entered the Royal Academy schools in 1828, and carried off the highest prizes open to the students. In 1829 he exhibited for the first time in the Royal Academy. Gradually he began to confine himself more exclusively to subject and historical pictures, varied occasionally by portraits of Campbell, Miss Landon, Dickens, and other of his literary friends. In 1833 he exhibited two pictures which greatly increased his reputation, and in 1835 the "Chivalric Vow of the Ladies and the Peacock" procured his election as associate of the Academy, of which he became full member in 1840. The years that followed were occupied with a long series of figure pictures, deriving their subjects from history and tradition and from the works of Shakespeare, Goldsmith and Le Sage. He also designed illustrations for several of Dickens's Christmas books and other works. Between the years 1830 and 1836 he contributed to Fraser's Magazine, under the pseudonym of Alfred Croquis, a remarkable series of portraits of the literary and other celebrities of the time—character studies, etched or lithographed in outline, and touched with the kind of caricature which were afterwards published as the Macleise Portrait Gallery (1871). In 1858 Macleise commenced one of the two great monumental works of his life, the "Meeting of Wellington and Blücher," on the walls of Westminster Palace. It was begun in fresco, a process which proved unmanageable. The artist wished to resign the task; but, encouraged by Prince Albert, he studied in Berlin the new method of "water-glass" painting, and carried out the subject and its companion, the "Death of Nelson," in that medium, completing the latter painting in 1864. The intense application which he gave to these great historic works, and various circumstances connected with the commission, had a serious effect on the artist's health. He began to shun the company in which he formerly delighted; his old buoyancy of
spirits was gone; and when, in 1865, the presidency of the Academy was offered to him he declined the honour. He died of acute pneumonia on the 25th of April 1876. His works are distinguished by powerful intellectual and imaginative qualities, but most of them are marked by harsh and dull colouring, by metallic hardness of surface and texture, and by frequent touches of the theatrical in the action and attitudes of the figures. His fame rests most securely on his two greatest works at Westminster.

A memoir of Maclise, by his friend W. J. O'Driscoll, was published in 1871.

MACLURE, WILLIAM (1763–1840), American geologist, was born at Ayr in Scotland in 1763. After a brief visit to New York in 1782 he began active life as a partner in a London firm of American merchants. In 1796 business affairs took him to Virginia, U.S.A., which he thereafter made his home. In 1803 he visited France as one of the commissioners appointed to settle the claims of American citizens on the French government; and during the few years then spent in Europe he applied himself with enthusiasm to the study of geology. On his return home in 1807 he commenced the self-imposed task of making a geological survey of the United States. Almost every state in the Union was traversed and mapped by him, the Alleghany Mountains being crossed and recrossed some fifty times. The results of his unaided labours were submitted to the American Philosophical Society in a memoir entitled Observations on the Geology of the United States explanatory of a Geological Map, and published in the Society's Transactions (vol. iv. 1809, p. 91) together with the first geological map of that country. This antedates William Smith's geological map of England by six years. In 1817 Maclure brought before the same society a revised edition of his map, and his great geological memoir was issued separately, with some additional matter, under the title Observations on the Geology of the United States of America. Subsequent survey has corroborated the general accuracy of Maclure's observations. In 1819 he visited Spain, and attempted, unsuccessfully, to establish an agricultural college near the city of Alicante. Returning to America in 1824, he settled for some years at New Harmony, Indiana, and sought to develop his scheme of the agricultural college. Failing health ultimately constrained him to relinquish the attempt, and to seek (in 1827) a more congenial climate in Mexico. There, at San Angel, he died on the 23rd of March 1840.

MACMAHON, MARIE EDMÉ PATRICE MAURICE DE, duke of Magenta (1808–1893), French marshal and president of the French republic, was born on the 13th of July 1808 at the château of Sully, near Autun. He was descended from an Irish family which went into exile with James II. Educated at the military school of St. Cyr, in 1827 he entered the army, and soon saw active service in the first French campaign in Algeria, where his ability and bravery became conspicuous. Being recalled to France, he gained renewed distinction in his expedition to Antwerp in 1832. He became captain in 1833, and in that year returned to Algeria. He led daring cavalry raids across plains infested with Bedouin, and especially distinguished himself at the siege of Constantine in 1837. From then until 1855 he was almost constantly in Algeria, and rose to the rank of general of division. During the Crimean War MacMahon was given the command of a division, and in September 1855 he successfully conducted the assault upon the Malakoff works, which led to the fall of Sebastopol. After his return to France honours were showered upon him, and he was made a senator. Desiring a more active life, however, and declining the highest command in France, he was once more sent out, at his own request, to Algeria, where he completely defeated the Kabyles. After his return to France he voted as a senator against the unconstitutional law for general safety, which was brought forward in consequence of Orsini's abortive attempt on the emperor's life. MacMahon greatly distinguished himself in the Italian campaign of 1859. Partly by good luck and partly by his boldness and sagacity in pushing forward without orders at a critical moment at the battle of Magenta, he enabled the French to secure the victory. For his brilliant services the MacMahon received his marshal's baton and was created duke of Magenta. In 1861 he represented France at the coronation of William I. of Prussia, and in 1864 he was nominated governor-general of Algeria. MacMahon's action in this capacity formed the least successful episode of his career. Although he did institute some reforms in the colonies, complaints were so numerous that twice in the early part of 1870 he sent in his resignation to the emperor. When the ill-fated Ollivier cabinet was formed the emperor abandoned his Algerian schemes and MacMahon was recalled.

War being declared between France and Prussia in July 1870, MacMahon was appointed to the command of the Alsace army detachment (see Franco-German War). On the 6th of August MacMahon fought the battle of Wörth (q.v.). His courage was always conspicuous on the field, but the two-to-one numerical superiority of the Germans triumphed. MacMahon was compelled to fall back upon Saverne, and hence to Toul. There, in his chateau of Saverne, he formed his base. Of his retreat, his movements were so ably conducted that the emperor confided to him the supreme command of the new levies which he was mustering at Châlons, and he was directed to effect a junction with Bazaine. This operation he undertook against his will.

He had an army of 120,000 men, with 324 guns; but large numbers of the troops were disorganized and demoralized. Early on the 1st of September the decisive battle of Sedan began. MacMahon was dangerously wounded in the thigh, whereupon General Ducrot, and soon afterwards General de Wimpffen, took command. MacMahon shared the captivity of his comrades, and resided at Wiesbaden until the conclusion of peace.

In March 1871 MacMahon was appointed by Thiers commander-in-chief of the army of Versailles; and in that capacity he suppressed the Communist insurrection, and successfully conducted the second siege of Paris. In the following December he was invited to become a candidate for Paris in the elections to the National Assembly, but declined nomination. On the resignation of Thiers as president of the Republic, on the 24th of May 1873, MacMahon was elected to the vacant office by an almost unanimous vote, being supported by 390 members out of 392. The duc de Broglie was empowered to form a Conservative administration, but the president also took an early opportunity of showing that he intended to uphold the sovereignty of the National Assembly. On the 5th of November 1873 General Changarnier presented a motion in the Assembly to confirm MacMahon's powers for a period of ten years, and to provide for a commission of thirty to draw up a form of constitutional law. The president consented, but in a message to the Assembly he declared in favour of a confirmation of his own powers for seven years, and expressed his determination to use all his influence in the maintenance of Conservative principles. After prolonged debates the Septennate was adopted on the 19th of November, by 378 votes to 320. There was no coup d'etat in favour of "Henri V," as had been expected, and the president resolved to abide by "existing institutions." One of his earliest acts was to receive the finding of the court-martial upon his old comrade in arms, Marshal Bazaine, whose death sentence he commuted to one of twenty years' imprisonment in a fortress. Though MacMahon's life as president of the Republic was that of the simplest possible character, his term of office was marked by many brilliant displays, while his wife was a leader in all works of charity and benevolence.

The president was very popular in the rural districts of France, through which he made a successful tour shortly after the declaration of the Septennate. But in Paris and other large cities his policy soon caused great dissatisfaction, the Republican party especially being alienated by press prosecutions and the attempted suppression of Republican ideas. Matters were at a comparative deadlock in the National Assembly, until the accession of some Orleanists to the Moderate Republican party
in 1875 made it possible to pass various constitutional laws. In May 1877, however, the constitutional crisis became once more acute. A peremptory letter of censure from MacMahon to Jules Simon caused the latter to resign with his colleagues. The duc de Broglie formed a ministry, but Gambetta carried a resolution in the Chamber of Deputies in favour of parliamentary government. The president declined to yield, and being supported by the Senate, he dissolved the Chamber, by decree, on the 25th of June. The prosecution of Gambetta followed for a speech at Lille, in which he had said "the marshal must, if the elections be against him, se soumettre ou se démettre." In a manifesto respecting the elections, the president referred to his successful government and observed, "I cannot obey the injunctions of the demagogy; I can neither become the instrument of Radicalism nor abandon the post in which the constitution has placed me." His confidence in the result of the elections was misplaced. Notwithstanding the great pressure put upon the constituencies by the government, the elections in October resulted in the return of 335 Republicans and only 198 anti-Republicans, the latter including 30 MacMahonists, 89 Bonapartists, 41 Legitimists, and 38 Orleanists. The president endeavoured to ignore the significance of the elections, and continued his reactionary policy. As a last resort he called to power an extra-parliamentary cabinet under General Rochebouet, but the Republican majority refused to vote supplies, and after a brief interval the president was compelled to yield, and to accept a new Republican ministry under Dufaure. The prolonged crisis terminated on the 14th of December 1877, and no further constitutional difficulties arose in 1878. But as the senatorial elections, held early in 1879, gave the Republicans an effective working majority in the Upper Chamber, they now called for the removal of the most conspicuous anti-Republicans among the generals and officials. The president refused to supersede them, and declined to sanction the law brought in with this object. Perceiving further resistance to be useless, however, MacMahon resigned the presidency on the 30th of January 1879, and Jules Grévy was elected as his successor.

MacMahon now retired into private life. Relieved from the cares of state, his simple and unostentatious mode of existence enabled him to pass many years of dignified repose. He died at Paris on the 17th of October 1893, in his eighty-sixth year. A fine, tall, soldierly man, of a thoroughly Irish type, in private life MacMahon was universally esteemed as generous and honourable; as a soldier he was brave and able, without decided military genius; as a politician he was patriotic and well-intentioned, but devoid of any real capacity for statescraft.

McMaster, John Bach (1852-), American historian, was born in Brooklyn, New York, on the 29th of June 1852. He graduated from the College of the City of New York in 1872, worked as a civil engineer in 1873-1877, was instructor in civil engineering at Princeton University in 1877-1885, and in 1883 became professor of American history in the university of Pennsylvania. He is best known for his History of the People of the United States from the Revolution to the Civil War (1883 seq.), a valuable supplement to the more purely political writings of Schouler, Von Holst and Henry Adams.

Macmillan, the name of a family of English publishers. The founders of the firm were two Scotchmen, Daniel Macmillan (1813-1857) and his younger brother Alexander (1818-1896). Daniel was a native of the Isle of Arran, and Alexander was born in Irvine on the 3rd of October 1818. Daniel was for some time assistant to the bookseller Johnson at Cambridge, but entered the employ of Messrs Seeley in London in 1837; in 1843 he began business in Aldersgate Street, and in the same year the two brothers purchased the business of Newby in Cambridge. They did not confine themselves to bookselling, but published educational works as early as 1843. In 1845 they became the proprietors of the more important business of Stevenson, in Cambridge, the firm being styled Macmillan, Barclay & Macmillan. In 1850 Barclay retired and the firm resumed the name of Macmillan & Co. Daniel Macmillan died at Cambridge on the 27th of June 1857. In that year an impetus was given to the business by the publication of Kingsley's Two Years' Age. A branch office was opened in 1856 in Henrietta Street, London, which led to a great extension of trade. These premises were surrendered for larger ones in Bedford Street, and in 1869 the buildings in St Martin's Street were opened. Alexander Macmillan died in January 1896. By his great energy and literary associations, and with the aid of his partners, there had been built up in little over half a century one of the most important publishing houses in the world. Besides the issue of many important series of educational and scientific works, they published the works of Kingsley, Huxley, Maurice, Tennyson, Lightfoot, Westcott, J. R. Green, Lord Roberts, Lewis Carroll, and of many other well-known authors. In 1868 they took over the old-established publishing house of R. Bentley & Son, and with it the works of Mrs Henry Wood, Miss Rhoda Broughton, The Ingoldsby Legends, and also Temple Bar and the Argosy. In 1893 the firm was converted into a limited liability company, its chairman being Frederick Macmillan (b. 1853), who was knighted in 1909. The American firm of the Macmillan Company, of which he was also a director, is a separate business.

See Thomas Hughes, Memoir of Daniel Macmillan (1882); A Bibliographical Catalogue of Macmillan & Co's Publications from 1843 to 1891, with portraits of the brothers Daniel and Alexander after Dickens and Ascanio Hubert Herkomer; also articles in Le Livre (September 1886), Publishers' Circular (January 14, 1893), the Bookman (May 1901), &c.

MacmonieS, Frederick William (186- ), American sculptor and painter, was born at Brooklyn, New York, on the 20th of September 1863. His mother was a niece of Benjamin West. At the age of sixteen MacMonnies was received as an apprentice in the studio of Augustus St Gaudens, the sculptor, where he remained for five years. In 1884 he went to Paris and thence to Munich, where he painted for some months. Returning to Paris next year he became the most prominent pupil of Falguère. His " Diana " brought him a mention at the Salon of 1886. Three life-sized figures of angels for the church of St Paul, New York, were followed by his " Nathan Hale," in the City Hall Park, New York, and a portrait of James S. T. Stranahan, for Brooklvyn. This last brought him a " second medal " in the Salon of 1891, the first time an American sculptor had been so honoured. In 1893 he was chosen to design and carry out the Columbian Fountain for the Chicago World's Fair, which placed him instantly in the front rank. His largest work is a decoration for the Memorial Arch to Soldiers and Sailors, in Prospect Park, Brooklyn, consisting of three enormous groups in bronze. In Prospect Park, Brooklyn, MacMonnies has also a large " Horse Tamer," a work of much distinction. A " Winged Victory " at the U.S. military academy at West Point, New York, is of importance; and his " Bacchante," an extraordinary combination of realism and imagination, rejected by the Boston Public Library, is now at the Metropolitan Museum of Art, New York. He also became well known as a painter, mainly of portraits. In 1888 he married Mary Fairchild, a figure painter of distinction, but in 1909 they were divorced and she married W. H. Low.

Macnaghten, Sir William Hay, Bart. (1793-1841), Anglo-Indian diplomatist, was the second son of Sir Francis Macnaghten, Bart., judge of the supreme courts of Madras and Calcutta. He was born in August 1793, and educated at Charterhouse. He went out to Madras as a cadet in 1800, but was appointed in 1816 to the Bengal Civil Service. He early displayed a great talent for languages, and also published several treatises on Hindu and Mahomedan law. His political career began in 1830 as secretary to Lord William Bentinck; and in 1837 he became one of the most trusted advisers of the governor-general, Lord Auckland, with whose policy of supporting Shah Shuja against Dost Mahommed, the reigning amir of Kabul, Macnaghten was closely identified. As political agent at Kabul he came into conflict with the military authorities and subsequently with his subordinate Sir Alexander Burnes. Macnaghten attempted to placate the Afghan chiefs with heavy subsidies, but when the drain on the Indian exchequer became too great,
and the allowances were reduced, this policy led to an outbreak. Burnes was murdered on the 2nd of November 1841; and owing to the incapacity of the aged General Elphinstone the British army in Kabul degenerated into a leaderless mob. Macnaghten tried to save the situation by negotiating with the Afghan chiefs and, independently of them, with Dost Mahommed's son, Akbar Khan, by whom he was assassinated on the 23rd of December 1841: the disastrous retreat from Kabul and the massacre of the British army in the Kurk Kabul pass followed. These events threw doubt on Macnaghten's capacity for dealing with the problems of Indian diplomacy, though his fearlessness and integrity were unquestioned. He had been created a baronet in 1840, and four months before his death was nominated to the governorship of Bombay.

**MacNally, Leonard** (1752–1820), Irish informer, was born in Dublin, the son of a merchant. In 1776 he was called to the Irish, and in 1783 to the English bar. He supported himself for some time in London by writing plays and editing the Public Ledger. Returning to Dublin, he entered upon a systematic course of informing against the members of the revolutionary party, for whom his house had become the resort. He also betrayed to the government prosecutors political clients whom he defended, often in the courts. In 1801 he was enominated, by Robert Emmet and cheered him in his last hours, although before appearing in court he had sold, for £200, the contents of his brief to the lawyers for the Crown. After living a professing Protestant all his life, he received absolution on his deathbed from a Roman Catholic priest. He died on the 15th of February 1820.

**Macnee, Sir Daniel** (1806–1882), Scottish portrait painter, was born at Fintry in Stirlingshire. At the age of thirteen he was apprenticed, along with Horatio Macculloch and Leitch the water-colour painter, to John Knox, a landscapist of some repute. He afterwards worked for a year as a lithographer, was employed by the Smiths of Cumnock to paint the ornamental lids of their pianoforte snuff-boxes, and, having studied in Edinburgh at the "Trustees' Academy," supported himself meanwhile by designing and colouring book illustrations for Lizar's engraver, he established himself as an artist in Glasgow, where he became a fashionable portrait painter. He was in 1829 admitted a member of the Royal Scottish Academy; and the death of Sir George Harvey in 1836 he was elected president, and received the honour of knighthood. From this period till his death, on the 18th of January 1882, he resided in Edinburgh, where his genial social qualities and his inimitable powers as a teller of humorous Scottish anecdote rendered him popular.

**Macneil, Hermon Atkins** (1866– ), American sculptor, was born at Chelsea, Massachusetts. He was an instructor in industrial art at Cornell University in 1886–1889, and was then a pupil of Henri M. Chapu and Falguière in Paris. Returning to America, he aided Philip Martyny in the preparation of sketch models for the Columbian exposition, and in 1896 he won the Rinchart scholarship, passing four years (1896–1900) in Rome. In 1906 he became a National Academician. His first important work was "The Moqui Runner," which was followed by "A Primitive Chant," "The Sun Vow," "The Indian Chant," "The Indian Tale," and "The Indian Dream." These works were successful, and he gained a reputation as a sculptor of Indian subjects. In 1909 he won in competition a commission for a large soldier's and sailor's monument in Albany, New York. His wife, Carol Brooks MacNeil, also a sculptor of distinction, was a pupil of F. W. MacMonnies.

**Mcneil, Hugh** (1795–1879), Anglican divine, younger son of Alexander McNeil (or McNeill), was born at Ballycastle, Co. Antrim, on the 15th of July 1795. He graduated at Trinity College, Dublin, in 1810. His handsome presence, and his promise of exceptional gifts of oratory, led a wealthy uncle, Major-General Daniel McNeil, to adopt him as his heir; and he was destined for a parliamentary career. During a stay at Florence, Hugh McNeil became temporarily intimate with Lord Byron and Madame de Staël. On returning home, he determined to abandon the prospect of political distinction for the clerical profession, and was disinherited. In 1820 he was ordained, and after holding the curacy of Stranorlar, Co. Donegal, for two years, was appointed to the living of Albury, Surrey, by Henry Drummond.

Edward Irving endeavoured, not without success at first, to draw McNeil into agreement with his doctrine and aims. Irving's increasing extravagance, however, soon alienated McNeil. His preaching now attracted much attention; in London he frequently was heard by large congregations. In 1834 he accepted the incumbency of St Jude's, Liverpool, where for the next thirty years he wielded great political as well as ecclesiastical influence. He repudiated the notion that a clergyman should be debarred from politics, maintaining at a public meeting that "God when He made the minister did not unmake the citizen." In 1835 McNeil entered upon a long contest, in which he was eventually successful, with the Liverpool corporation, which had been captured by the Whigs, after the passing of the Municipal Reform Act. A proposal was carried that the elementary schools were to be conducted by the Church of England, and he introduced what was known as the Irish National System. The threatened withdrawal of the Bible as the basis of denominational religious teaching was met by a fierce agitation led by McNeil, who so successfully enlisted public support that before the new system could be introduced every child was provided for in the new Church of England schools established by public subscriptions. At the same time he conducted a campaign which gradually reduced the Whig element in the council, till in 1841 it almost entirely disappeared. To his influence was also attributed the defeat of the Liberal parliamentary candidates in the general election of 1837, followed by a long period of Conservative predominance in Liverpool politics. McNeil had the Irish Protestant's horror of Romanism, which he constantly denounced in the pulpit and on the platform; and Macaulay, speaking in the House of Commons on the Maynooth endowment in April 1845, singled him out for attack as the most powerful representative of uncompromising Protestant opinion in the country. As the Tractarian movement in the Church of England developed, he became one of its most zealous opponents and the most conspicuous leader of the evangelical party. In 1840 he published a volume of Lectures on the Church of England, and in 1846 (the year after Newman's secession to Rome) The Church and the Churches, in which he maintained with much dialectical skill the evangelical doctrine of the "invisible Church" in opposition to the teaching of Newman and Pusey. Hugh McNeil was in close sympathy with the philanthropic work as well as the religious views of the 7th earl of Shaftesbury, who more than once tried to persuade Lord Palmerston to raise him to the episcopal bench. But although Palmerston usually followed the advice of Shaftesbury in the appointment of bishops, he would not consent to the elevation to the House of Lords of so powerful a political opponent as McNeil, whom Lord John Russell had accused of frustrating for thirty years the education policy of the Liberal party. In 1860 he was appointed a canon of Chester; and in 1868 Disraeli appointed him dean of Ripon. This preference he resigned in 1875, and he lived in retirement at Bournemouth till his death on the 26th of January 1879. McNeil married, in 1822, Anne, daughter of William Magee, bishop of Dublin, and aunt of William Connor Magee, bishop of York, by whom he had a large family.

Although a vehement controversialist, Hugh McNeil was a man of simple and sincere piety of character. Sir Edward Russell, an opponent alike of his religious and his political opinions, bears witness to the deep spirituality of his teaching, and describes him as an absolutely unique personality. "He made himself leader of the Liverpool people, and always led with calm and majesty in the most excited times. His eloquence was grave, flowing, emphatic—had a dignity in delivery, a perfection of elocution, that only John Bright equalled in the latter half of the
19th century. Its fire was solemn force. McNeill’s voice was probably the finest organ ever heard in public oratory. His action was as graceful as it was expressive. He ruled an audience.”

MACNEILL, HECTOR (1746-1818). Scottish poet, was born near Roslin, Midlothian, on the 22nd of October 1746, the son of an impoverished army captain. He went to Britain at the age of fourteen, and soon afterwards was despatched to the West Indies. From 1750 to 1786 he acted as assistant secretary on board the flagship of Admiral Gery and Sir Richard Bickerton (1772-1792). Most of his later life was spent in Scotland, and it was in the house of a friend at Stirling that he wrote most of his songs and his Scotland’s Skail, or the History of Will and Jean (1795), a narrative poem intended to show the deteriorating influences of whisky and pothouse politics. A sequel, The Weas of War, appeared next year. In 1800 he published The Memoirs of Charles Macpherson, Esq., a novel understood to be a narrative of his own hardships and adventures. A complete edition of the poems he wished to own appeared in 1812. His songs “Mary of Castlecary”, “Come under my plaidy,” “My boy Tammy,” “O tell me how to wo,” “I lo’d ne’er a lassie but aye,” “The plaid amang the herd,” and “Jeanie’s black e’e,” are notable for their sweetness and simplicity. He died Edinburgh on the 13th of March, 1828.

Macon, a city and the county-seat of McDonough county, Illinois, U.S.A., in the W. part of the state, about 60 m. S.W. of Peoria. Pop. (1890), 4052; (1900), 5375 (232 foreign-born); (1910), 5774.

Macon is served by the Chicago, Burlington & Quincy, and the Macon & Western Illinois railways. The city is the seat of the Western Illinois state normal school (opened in 1902), and has a Carnegie library and a city park. Clay is found in the vicinity, and there are manufactures of pottery, bricks, &c. The city was founded in 1820 as the county-seat of McDonough county, and was called Washington by the settlers, but the charter of incorporation, also granted in 1830, gave it the present name in honour of General Alexander Macomb. Macon was first chartered as a city in 1836.

MACOMER, a village of Sardinia in the province of Cagliari, from which it is 95 m. N.N.W. by rail, and the same distance S.W. of Golfo degli Aranci. Pop. (1901) 988. It is situated on the coast 1800 ft. above sea-level on the southern ascent to the central plateau (the Campeda) of this part of Sardinia; and it is the junction of narrow-gauge lines branching from the main line eastwards to Nuoro and westwards to Bosa. The old parish church of S. Pantaleone has three Roman mile-stones in front of it, belonging to the Roman high-road from Carales to Turris Libisonis. The modern high-road follows the ancient. The district, especially the Campeda, is well fitted for grazing and horse and cattle breeding, which is carried on to a considerable extent. It is perhaps richer in nuraghi than any other part of Sardinia.

MACON, NATHANIEL (1758-1837), American political leader, was born at Macon Manor, Warren county, North Carolina, on the 17th of December 1758. He studied at the college of New Jersey (now Princeton University) from 1774 to 1776, when the institution was closed on account of the outbreak of the War of Independence; served for a short time in a New Jersey militia company; studied law at Bute Court-house, North Carolina, in 1777-1780, at the same time managing his tobacco plantation; was a member of a Warren county militia company in 1780-1782, and served in the North Carolina Senate in 1781-1785. In 1786 he was elected to the Continental Congress, but declined to serve. In 1791-1815 he was a member of the national House of Representatives, and in 1815-1828 of the United States Senate. Macon’s point of view was always local rather than national. He was essentially a North Carolina first, and an American afterwards; and throughout his career he was an aggressive advocate of state sovereignty and an adherent of the doctrines of the “Old Republicans.” He at first opposed the adoption of the Federal constitution of 1787, as a member of the faction led by Willie Jones (1731-1801) of Halifax, North Carolina, but later withdrew his opposition. In Congress he denounced Hamilton’s financial policy, opposed the Jay Treaty (1793) and the Alien and Sedition Acts, and advocated a continuance of the French alliance of 1778. His party came into power in 1801, and he was Speaker of the house from December 1801 to October 1807. At first he was in accord with Jefferson’s administration; he approved the Louisiana Purchase, and as early as 1803 advocated the purchase of Florida. For a number of years, however, he was politically allied with John Randolph. As speaker, in spite of strong opposition, he kept Randolph at the head of the important committee on Ways and Means from 1801 to 1806; and in 1805-1808, with Randolph and Joseph H. Nicholson (1770-1817) of Maryland, he was a leader of the group of about ten independents, called the “Quids,” who strongly criticized Jefferson and opposed the presidential candidature of Madison. By 1809, however, Macon was again in accord with his party, and during the next two years he was one of the most influential of its leaders. In December 1809 he introduced resolutions which combined the ideas of Peter Early (1773-1817) of Georgia, David R. Williams (1776-1830) of South Carolina, and Samuel W. Dana (1757-1830) of Connecticut with his own. The resolutions recommended the complete exclusion of foreign vessels from United States ports, the suppression of illegal trade carried on by foreign merchants under the American flag. The substance of these resolutions was embodied in the “Macon Bill, No. 1,” which passed the House but was defeated in the Senate. On the 7th of April 1810 Macon reported from the committee the “Macon Bill, No. 2,” which had been drawn by John Taylor (1770-1832) of South Carolina, and was not actively supported by him. This measure (amended) became law on the 1st of May, and provided for the repeal of the Non-Intercourse Act of 1809, authorized the president, “in case either Great Britain or France shall before the 3rd day of March next so revoke or modify her edicts as that they cease to violate the neutral commerce of the United States,” to revive non-intercourse against the other, and prohibited British and French vessels of war from entering American waters. In 1812 Macon voted for the declaration of war against Great Britain, and later was chairman of the Congressional committee which made a report (July 1812) condemning Great Britain’s conduct of the war. He opposed the Bank Act of 1816, the “internal improvements” policy of Calhoun (in the early part of his career) and Clay, and the Missouri Compromise, his speech against the last being especially able. In 1824 Macon received the electoral vote of Virginia for the vice-presidency, and in 1826-1828 was president pro tempore of the Senate. He was president of the North Carolina constitutional convention in 1835, and was an elector on the Van Buren ticket in 1836. He died at his home, Buck Springs, Warren county, North Carolina, on the 29th of June 1837.

See William E. Dodd, The Life of Nathaniel Macon (Raleigh, N.C., 1894), and E. M. Wilson, The Congressional Career of Nathaniel Macon (Cassel Hill, N.C., 1900).

MÁCON, a town of east-central France, capital of the department of Saône-et-Loire, 45 m. N. of Lyons on the Paris-Lyon railway. Pop. (1906), 16,515. Mâcon is situated on the right bank of the Saône facing the plain of the Bresse; a bridge of twelve arches connects it with the suburb of St Laurens on the opposite bank. The most prominent building is the modern Romanesque church of St Pierre, a large three-naved basilica, with two fine spires. Of the old cathedral of St Vincent (12th and 13th centuries), destroyed at the Revolution, nothing remains but the Romanesque narthex, now used as a chapel, the façade and its two flanking towers. The hôtel de ville contains a library, a theatre and picture-galler. Opposite to it stands a statue of the poet Alphonse Lamartine, a native of the town. Mâcon is the seat of a prefecture, and has tribunals of first instance and of commerce, and a chamber of commerce. There are

1 Their names are associated in Randolph-Macon College, named in their honour in 1830.
MACON—MACPHERSON, J. 267

lycées and training colleges. Copper-founding is an important industry; manufactures include cakes, mats, rope and utensils for the vine-trade. The town has a large trade in wine of the district, known as Macon. It is a railway centre of considerable importance, being the point at which the line from Paris to Marseilles is joined by that from Mont Cenis and Geneva, as well as by a branch from Moulins.

Macon (Matisco) was an important town of the Aedui, but under the Romans it was supplanted by Autun and Lyons. It suffered a succession of disasters at the hands of the Germans, Burgundians, Vandals, Huns, Hungarians and even of the Carolingian kings. In the feudal period it was an important county which in 1228 was sold to the king of France, but more than once afterwards passed into the possession of the dukes of Burgundy, until the ownership of the French crown was established in the time of Louis XI. In the 16th century Macon became a stronghold of the Huguenots, but afterwards fell into the hands of the League, and did not yield to Henry IV. until 1594. The bishopric, created by King Childebert, was suppressed in 1790.

MACON, a city and the county-seat of Bibb county, Georgia, U.S.A., in the central part of the state, on both sides of the Ocmulgee river (at the head of navigation), about 90 m. S.S.E. of Atlanta. Pop. (1900), 23,272, of whom 11,550 were negroes; (1910 census) 40,665. Macon is, next to Atlanta, the most important railway centre in the state, being served by the Southern, the Central of Georgia, the Georgia, the Georgia Southern & Florida, the Macon Dublin & Savannah, and the Macon & Birmingham railways. It was formerly an important river port, especially for the shipment of cotton, but lost this commercial advantage when railway bridges made the river impassable. It is, however, partially regaining the river trade in consequence of the compulsory substitution of drawbridges for the stationary railway bridges. The city is the seat of the Wesleyan female college (1836), which claims to be the first college in the world chartered to grant academic degrees to women; Mercer University (Baptist), which was established in 1853 as Mercer Institute at Penfield, became a university in 1857; was removed to Macon in 1871, and controls Hearn Academy (1839) at Cave Spring and Gibson Mercer Academy (1803) at Bowman; the state academy for the blind (1852), St Stanislaus’ College (Jesuit), and Mt St de Sales Academy (Roman Catholic) for women. There are four orphan asylums for whites and two for negroes, supported chiefly by the Protestant Episcopal and Methodist Churches, and a public hospital. Immediately east of Macon are two large Indian mounds, and there is a third mound 9 m. south of the city. Situated in the heart of the "Cotton Belt," Macon has a large and lucrative trade; it is one of the most important inland cotton markets of the United States, its annual receipts averaging about 250,000 bales. The city’s factory products in 1905 were valued at $7,997,347 (33.8% more than in 1900). In the vicinity are large beds of kaolin, 30 m. wide, reaching nearly across the state, and frequently 35 to 70 ft. in depth. Macon is near the fruit-growing region of Georgia, and large quantities of peaches and of other fruit products are annually shipped from the city.

Macon (named in honour of Nathaniel Macon) was surveyed in 1823 by order of the Georgia legislature for the county-seat of Bibb county, and received its first charter in 1824. It soon became the centre of trade for Middle Georgia; in 1833 a steamboat line to Darien was opened, and in the following year 60,000 bales of cotton were shipped by this route. During the Civil War the city was a centre for Confederate commissary supplies and the seat of a Treasury depository. In July 1864 General George Stoneman (1822–1864) with 500 men was captured near the city by the Confederate general, Howell Cobb. Macon was finally occupied by Federal troops under General James H. Wilson (b. 1837) on the 20th of April 1864. In 1900–1910 the area of the city was increased by the annexation of several suburbs.

MACPHERSON, SIR DAVID LEWIS (1818–1896), Canadian financier and politician, was born at Castle Leathers, near Inverness, Scotland, on the 17th of September 1818. In 1835 he emigrated to Canada, settling in Montreal, where he built up a large fortune by "forwarding" merchandise. In 1853 he removed to Toronto, and in the same year obtained the contract for building a line of railway from Toronto to Sarnia, a project from which sprang the Grand Trunk railway, in the construction of which line he greatly increased his wealth. In 1864 he was elected to the Canadian parliament as member of the Legislative Council for Saugeen, and on the formation of the Dominion, in 1867, was nominated to the Senate. In the following years he published a number of pamphlets on economic subjects, of which the best-known is Banking and Currency (1869). In 1880 he was appointed Speaker of the Senate, and from October 1883 till 1885 was minister of the interior in the Conservative cabinet. In 1884 he was knighted by Queen Victoria. He died on the 16th of August 1896.

MACPHERSON, JAMES (1736–1790), Scottish "translator" of the Ossianic poems, was born at Ruthven in the parish of Kingsussie, Inverness, on the 27th of October 1736. He was sent in 1753 to King's College, Aberdeen, removing two years later to Marischal College. He also studied at Edinburgh, but took no degree. He is said to have written over 4000 lines of verse while a student, but though some of this was published, notably The Highlander (1758), he afterwards tried to suppress it. On leaving college he taught in the school of his native place. At Moffat he met John Home, the author of Douglas, for whom he recited some Gaelic verses from memory. He also showed him MSS. of Gaelic poetry, supposed to have been picked up in the Highlands, and, encouraged by Home and others, he produced a number of pieces translated from the Gaelic, which he was induced to publish at Edinburgh in 1760 as Fragments of Ancient Poetry collected in the Highlands of Scotland. Dr Hugh Blair, who was a firm believer in the authenticity of the poems, got up a subscription to allow Macpherson to pursue his Gaelic researches. In the autumn he set out to visit western Inverness, the islands of Skye, North and South Uist and Benbecula. He obtained MSS. which he translated with the assistance of Captain Morrison and the Rev. A. Gallie. Later in the year he made an expedition to Mull, when he obtained other MSS. In 1761 he announced the discovery of an epic on the subject of Fingal, and in December he published Fingal, an Ancient Epic Poem in Six Books, together with Several Other Poems composed by Ossian, the Son of Fingal, translated from the Gaelic Language, written in the musical measured prose of which he had made use in his earlier volume. Temora followed in 1763, and a collected edition; The Works of Ossian, in 1765.

The genuineness of these so-called translations from the works of a 3rd-century bard was immediately challenged in England, and Dr Johnson, after some local investigation, asserted (Journey to the Western Islands of Scotland, 1775) that Macpherson had only found fragments of ancient poems and stories, which he had woven into a romance of his own composition. Macpherson is said to have sent Johnson a challenge, to which Johnson replied that he was not to be deterred from detecting what he thought a deceit, and proceeded to publish his originals, which he refused to publish on the ground of the expense. In 1764 he was made secretary to General Johnstone at Pensacola, West Florida, and when he returned, two years later, to England, after a quarrel with Johnstone, he was allowed to retain his salary as a pension. He occupied himself with writing several historical works, the most important of which was Original Papers, containing the Secret History of Great Britain from the Restoration to the Accession of the House of Hanover; to which are prefixed Extracts from the Life of James II., as written by himself (1775). He enjoyed a salary for defending the policy of Lord North’s government, and held the lucrative post of London agent to Mohammad Ali, nabob of Aroet. He entered parliament in 1780, and continued to sit until his death. In his later years he bought an estate, to which he gave the name of Belville, in his native county of Inverness, where he died on the 17th of February 1796.

After Macpherson's death, Malcolm Laing, in an appendix to his History of Scotland (1800), propounded the extreme view that...
the so-called Ossianic poems were altogether modern in origin, and that Macpherson's authorities were practically non-existent. For a discussion of this question see C. L. MACREADY—

confounds and books. Any of the Ossianic poems do not alter the fact that he produced a work of art which by its deep appreciation of natural beauty and the melancholy tenderness of its treatment of the ancient legend did more than any single work to bring about the romantic movement in European, and especially in German, literature. It was speedily translated into many European languages, and Herder and Goethe (in his earlier period) were among its profound admirers. Casoratti's Italian translation was one of Napoleon's favourite books.

AUTHORS.—For Macpherson's life, see The Life and Letters of James Macpherson. (1894, n.d. 1900), by Rev. J. H. Saunders, who has laboured to redeem his character from the suspicions generally current with English readers. The antiquity of the Ossianic poems was defended in the introduction by Archibald Clephane, in The Poems of Ossian (1796); Materials for arriving at a decision by comparison with undoubtedly genuine fragments of the Ossianic legend are available in The Book of the Dead of Lismore, Gaelic verses, collected by J. McGregor, dean of Lismore, in The Poems and Fragments of Ossian (1801); T. N. De Foin, inL'authenticité des Œuvres d'Ossian (1813); J. M. F. de Feinze (1871) of F. J. Campbell, who also discusses the subject in Popular Tales of the Western Highlands, iv. (1893). See also L. C. Stern, "Die oasianischen Heldenlieder in Zeitschrift für vergleichende Literaturwissenschaft, Abhandlung (1895); Eng. trans. by J. L. Robertson in Trans. Gud. Soc. of Inverness, xxii, 1897-1898; Sir J. Sinclair, A Dissertation on the Authenticity of the Poems of Ossian (1806); Transactions of the Ossianic Society (Dublin, 1854-1861); Cours de littérature comparée, by D. Roberts, ed. du recueil (1883, &c.); A. N. Ossian and the Ossianic Literature (1890), with a valuable bibliographical appendix; J. S. Smart, James Macpherson: an Epistle in Literature (1905).

MCPHERSON, JAMES BIRDSEYE (1828-1864). American soldier, was born at Sandusky, Ohio, on the 14th of November 1828. He entered West Point at the age of twenty-one, and graduated (1853) at the head of his class, which included Sheridan, Schofield and Hood. He was employed at the military academy as instructor of practical military engineering (1853). A year later he was sent to engineer duty at New York, and in 1857, after constructing Fort Delaware, he was sent as superintendent engineer to San Francisco, becoming 1st lieutenant in 1858. He was promoted captain during the first year of the Civil War, and towards the close of 1861 became lieutenant-colonel and aide-de-camp to General Halleck, who in the spring of 1862 sent him to General Grant as chief engineer. He remained with Grant during the Shiloh campaign, and acted as engineer adviser to Halleck during the siege operations against Corinth in the summer of 1862. In October he distinguished himself in command of an infantry brigade at the battle of Corinth, and on the 8th of this month was made major-general of volunteers and commander of a division. In the second advance on Vicksburg (1863) McPherson commanded the XVII corps, fought at Port Gibson, Raymond and Jackson, and after the fall of Vicksburg was strongly recommended by Grant for the rank of brigadier-general in the regular army, to which he was promoted on the 1st of August 1863. He continued to display conspicuous ability, and was permitted to go on leave of absence in order to be married in Baltimore when he received his nomination to the command of the Army of the Tennessee, Grant's and Sherman's old army, which was to take part under Sherman's supreme command in the campaign against Atlanta (1864). This nomination was made by Sherman and entirely approved by Grant, who had the highest opinion of McPherson's military and personal qualities. He was in command of his army at the actions of Resaca, Dallas, Kenesaw Mountain and the battles about Atlanta. On the 22nd of July, when the Confederates under his old classmate Hood made a sudden and violent attack on the lines held by the Army of the Tennessee, McPherson rode up, in the woods, to the enemy's firing line and was killed. He was one of the most heroic figures of the American Civil War, and Grant is reported to have said when he heard of McPherson's death, "The country has lost one of its best soldiers, and I have lost my best friend."

MACQUARIE, a British island in the South Pacific Ocean, in 24° 49' S. and 159° 45' E. It is about 20 m. long, and covered with arid, sandy vegetation, with some trees or shrubs in the sheltered places which afford food to a parrot of the genus Cyanoramphus, allied to those of the Auckland Islands. Although it has no settled population, Macquarie is constantly visited by sailors in quest of the seals which abound in its waters.

MACRAUCHENIA, a long-necked and long-limbed, three-toed South American ungulate mammal, typifying the suborder Litopterna (q.v.).

MACREARY, WILLIAM CHARLES (1793-1873), English actor, was born in London on the 3rd of March 1793, and educated at Rugby. It was his intention to go up to Oxford, but in 1809 the embarrassed affairs of his father, the lessee of several provincial theatres, called him to share the responsibilities of theatrical management. On the 7th of June 1810 he made a successful first appearance as Romeo at Birmingham. Other Shakespearian parts followed, but a serious rupture between father and son resulted in the young man's departure for Bath and Madrid in 1812. For a time he lived with a professional connection of his father's at Madrid, and after the close of the famous visit to other provincial towns, on the 16th of September 1816, Macready made his first London appearance at Covent Garden as Orestes in The Distressed Mother, a translation of Racine's Andromaque by Ambrose Phillips. Macready's choice of characters was at first confined chiefly to the romantic drama. In 1818 he won a permanent success in Isaac Pocock's (1782-1835) adaptation of Scott's Rob Roy. He showed his capacity for the highest tragedy when he played Richard III, at Covent Garden on the 25th of October 1819. Transferring his services to Drury Lane, he gradually rose in public favour, his most conspicuous success being in the title-role of Sheridan Knowles's William Tell (May 11, 1825). In 1826 he completed a successful engagement in America, and in 1828 his performances met with a very flattering reception in Paris. On the 15th of December 1830 he appeared at Drury Lane as Werner, one of his most powerful impersonations. In 1833 he played in Antony and Cleopatra, in Byron's Sardanapalus, and in King Lear. Already Macready had done something to encourage the creation of a modern English drama, and after entering on the management of Covent Garden in 1837 he introduced Robert Browning's Straford, and in the following year Bulwer's Lady of Lyons and Richelieu, the principal characters in which were among his most effective parts. On the 10th of June 1838 he gave a memorable performance of Henry V., for which Stanfield prepared sketches, and the mounting was superintended by Bulwer, Dickens, Forster, Maclise, W. J. Fox and other friends. The first production of Bulwer's Money took place under the artistic direction of Count d'Oursay on the 8th of December 1840, Macready winning unmistakable success in the character of Alfred Evelyn. Both in his management of Covent Garden, which he resigned in 1839, and of Drury Lane, which he held from 1841 to 1843, he found his designs for the elevation of the stage frustrated by the absence of adequate public support. In 1843-44 he made a prosperous tour in the United States. On his return, on his visit to that country, in 1849, was married by a riot at the Astor Opera House, New York, arising out of the jealousy of the actor Edwin Forrest, and resulting in the death of seventeen persons, who were shot by the military called out to quell the disturbance. Macready took leave of the stage in a farewell performance of Macbeth at Drury Lane on the 26th of February 1851. The remainder of his life was spent in happy retirement, and he died at Cheltenham on the 27th of April 1873. He had married, in 1823, Catherine Frances Atkins (d. 1852). Of a numerous family of children only one son and one daughter survived. In 1860 he married Cecile Louise Frederica Spencer (1827-1908), by whom he had a son.

Macready's performances always displayed fine artistic perceptions developed to a high degree of perfection by very comprehensive culture, and even his least successful personalities had the interest resulting from thorough intellectual
study. He belonged to the school of Kean rather than of Kemble; but, if his tastes were better disciplined and in some respects more refined than those of Kean, his natural temperament did not permit him to give proper effect to the great tragic parts of Shakespeare, *King Lear* perhaps excepted, which afforded scope for his pathos and tenderness, the qualities in which he specially excelled. With the exception of a voice of good nature and a delicate sense of very varied expression, Macready had no special physical gifts for acting, but the defects of his face and figure cannot be said to have materially affected his success.

MACROBIUS, AMBROSIO THEODOSIUS, Roman grammarian and philosopher, flourished during the reigns of Honorius and Arcadius (395-423). He himself states that he was not a Roman, but there is no certain evidence whether he was of Greek or perhaps African descent. He is generally supposed to have been praetorius praefect in Spain (399), proconsul of Africa (410), and lord chamberlain (422). But the tenure of high office at that date was limited to Christians, and there is no evidence in the writings of Macrobius that he was a Christian. Hence the identification is more than doubtful, unless it be assumed that his conversion to Christianity was subsequent to the composition of his books. It is possible, but by no means certain, that he was the Theodosius to whom Avianus dedicates his fables.

The most important of his works is the *Saturnalia*, containing an account of the discussions held at the house of Vettius Praetextatus (c. 325-385) during the holiday of the Saturnalia. It was written by the author for the benefit of his son Eustathius (or Eustachius), and contains a great variety of curious historical, mythological, critical and grammatical disquisitions. There is but little attempt to give any dramatic character to the dialogue; in each book some one of the personages takes the leading part, and the remarks of the others serve only as occasional for calling forth fresh displays of erudition. The first book is devoted to an inquiry as to the origin of the Saturnalia and the festivals of Janus, which leads to a history and discussion of the Roman calendar, and to an attempt to derive all forms of worship from that of the sun. The second book begins with a collection of *bons mots*, to which all present make their contributions, many of them being ascribed to Cicero and Augustus; a discussion of various pleasures, especially of the senses, then seems to have taken place, but almost the whole of this is lost. The third, fourth, fifth and sixth books are devoted to Virgil, dwelling respectively on his learning in religious matters, his rhetorical skill, his debt to Homer (with a comparison of the art of the two) and to other Greek writers, and the nature and extent of his borrowings from the earlier Latin poets. The latter part of the third book is taken up with a dissertation upon luxury and the sumptuary laws intended to check it, which is probably a dislocated portion of the second book. The seventh book consists largely of the discussion of various physiological questions. The value of the work consists solely in the facts and opinions discussed, for it is part of a compilation, and has little in its literary form to recommend it. The form of the *Saturnalia* is copied from Plato’s *Symposium* and Gellius’s *Notus atticeae*; the chief authorities (whose names, however, are not quoted) are Gellius, Seneca the philosopher, Plutarch (*Quaestiones convivialiae*), Athenaeus and the commentators of Servius (excluded by some) and others on Virgil. We have also two books of a commentary on the *Somnium Scipionis* narrated by Cicero in his *De republica*. The nature of the dream, in which the elder Scipio appears to his (adopted) grandson, and describes the life of the good after death and the constitution of the universe from the Stoic point of view, gives occasion for Macrobius to discourse upon many points of physics in a series of essays interesting as showing the astronomical notions then current. The moral elevation of the fragment of Cicero thus preserved to us gave the work a popularity in the middle ages to which its own merits have little claim. Of a third work, *De differentiis et societatis graeci latini verbi*, we only possess an abstract by a certain Johannes, identified with Johannes Scotus Erigena (9th century).

MADÁCH, IMRE (1829-1864), Hungarian dramatist, was born at Alsó-Szegrevo. He took part in the great revolution of 1848-49 and was imprisoned; on his return to his small estate in the county of Nógrád, he found that his family life had meanwhile been completely wrecked. This only increased his natural tendency to melancholy, and he withdrew from public life till 1861, devoting his time mainly to the composition of his chief work, *Az ember tragediája* ("The Tragedy of Man"). John Arany, then at the height of his fame as a poet, at once recognized the great merits of that peculiar drama, and Madách enjoyed a short spell of fame before his untimely death of heart-disease in 1864. In *The Tragedy of Man* Madách takes us from the hour when Adam and Eve were innocently walking in the Garden of Eden to the times of the Pharaohs; then to the Athens of the Milesiads; to declining Rome; to the period of the crusades; into the study of the astronomer Kepler; thence into the horrors of the French Revolution; into greedy-eaten and commerce-ridden modern London; nay, into the ultra-Socialist state of the future, when all the former ideals of man will by scientific formulæ be shown up in their hollowness; still further, the poet shows the future of ice-clad earth, when man will be reduced to a degraded brute dragging on the
misery of his existence in a cave. In all these scenes, or rather anticipatory dreams, Adam, Eve and the arch-fiend Lucifer are the chief and constantly recurring *personae dramatis*. In the end, Adam, despairing of his race, wants to commit suicide, when at the critical moment Eve tells him that she is going to be a mother. Adam then prostrates himself before God, who encourages him to hope and trust. The diction of the drama is elevated and pure, and although not meant for the stage, it has proved very effective at several public performances.

Concerning Madagascar there is ample literature, consisting mostly of elaborate articles by Charles Szasz (1862), Augustus Groggus (1872), B. Alexander (1871), M. Pallágyi (1890), and others.

**Madagascar**, an island in the Indian Ocean, and after New Guinea and Borneo the largest island in the world, about 260 m. distant, at the nearest point, from the S.E. coast of Africa, from which it is separated by the Mozambique Channel. Since 1896 Madagascar has been a French colony. It is 995 m. in length from N. to S., and about 250 m. in average breadth, although near the town it is nearly 360 m. across; its area is about 228,000 sq. m., or not quite four times the extent of England and Wales. It lies mainly between 4° and 50° E. Its northernmost point, Cape Ambro, in 25° S., inclines 16° to the E. from the longitude of Cape St. Mary, the southernmost point, in 25° 35′ S., so that the main axis of the island runs from N.N.E. to S.S.W. In its broad structure Madagascar consists of an elevated mountainous region, from 3000 to 5000 ft. in altitude, occupying from two-fifths to a half of the centre and the eastern side of the island, around which are extensive plains at a much less elevation above the sea, and most developed on the western and north-west sides. But this lower region is broken up by masses of hills, with several elevated plateaus, especially in the south-west and south.

**Physical Features.**—Madagascar has a very regular and compact form, with few indentations considering its great extent of shore-line. In general it is a high island, having an average altitude of 400 ft. above sea level, and the mountainous foot—the left side. Along two-thirds of its eastern side the coast is almost a straight line, without any inlet, Tamatave, the chief port on this side of the island, being only protected by coral reefs. North of this line, however, is Antongil Bay, a deep and wide inlet running for about 70 m. northwards. Low and almost flat at the extreme point of the island is Diego-Suarez Bay, one of the finest harbours in the world. But the north-western side of Madagascar is broken up by a number of bays, some of them land-locked, and others indentations of Cape St. Mary, the north-west angle of the island, the coast-line is unbroken until the estuary of the river Onliahry, or Saint Augustine's Bay, is reached. Rounding the southern end of the island, there is no other inlet save Diego-Suarez Bay, near the southern end of the straight line of coast already mentioned.

The islands around Madagascar are few and unimportant. The largest is Ste. Marie, near the eastern coast, a narrow island about 35 m. long and 8 m. broad, with a large and more compact in form, opposite Ampàshindàva Bay on the N.W. coast. East of the Minnow group, north of Nosibé, the rest are merely rocky islets, chiefly of coral.

The shores of the greater portion of the southern half of the island are low and flat, but in the northern half the coast is often bold and precipitous, the high land occasionally approaching the sea. On the eastern side the plains vary from 10 to 50 m. in breadth, but on the west side they extend in a level plain from 100 m. to 200 m. across, the coast-plains the ground rises by successive ranges of hills to the high interior land. This elevated region is broken in all directions by mountains, from which the crystalline rocks show most frequently as high crests and terraced ranges. The valleys are narrow and with little trace of irrigation, resembling Titanic castles, cathedrals, domes, pyramids and spires. The highest mountain mass is centrally situated as regards the length of the island, but more to the eastern side. This is the ancient extinct volcano Ankaratra, three of the highest peaks varying in elevation from 7284 to 8635 ft. above the sea, and from 3000 to 5000 ft. above the general level of the surrounding country. The lowest of these is named Tsia-ja-favina, i.e. "That which the mischievous one, who is in the mountain, has cut off." Amboró, in the northern province of Atsimo, is about 9400 ft. in altitude. Besides these highest points there are a considerable number of mountains varying from 3000 to 5000 ft. in their elevation, intervening and surrounding districts; and in the Bâa country the Isalà range has been compared to the "Church Buttes" and other striking features of the scenery of Utah. One of the finest of the Madagascar mountains is an isolated mass near the northern part of the island called Ambôbîhitra. This is 4460 ft. high, and rising from land little above the sea-level, is well seen far out to sea.

In the elevated region of Madagascar are many fertile plains and valleys, the former being the dried-up beds of ancient lakes. Among the most extensive are the Antananarivo and the Ankàrà districts, supplying a large proportion of the rice required for the capitals of these two provinces. Still more spacious valleys are the Antsianaka country and the Ankày district, between the two eastern mountains. The highest peaks of the island are chiefly in Ibôna (N.W.) and in Menâbôô (S. of the Tsirihina River); those on the east are widest in the Taîfâny country (S.E.). The water-parting for six-sevenths of the whole length of the island is much nearer the eastern than the western side, averaging from 80 to 90 m. in width, and divides the island into the Mananjary, Mangoro, with its great affluent Onivô, Vôhîra, Mannigôy, and the Antânambâlana at the head of Antongil Bay. On the N.W. coast, going southwards, the largest basin of the island is seated, the great river drains of the northern central province, forming unidentically the second largest river of the island and falling into Betsiboka Bay—the Mâhâvûy, Mânanbôô, Tsirihina or Ommânjûy, the third largest tributary of the Betsiboka, the Betsiboka, the Betsiboka, the Morôndava, Mangoky, probably the largest river in the country, accompanied by its important tributary the Mâtînàny, Mânantânana and Ranomafiu, the Fihêrêna and Onilâhy. On the south coast are the two holiest rivers of Madagascar, the Sambirano and the Betsiboka.

Of the western rivers the Betsiboka can be ascended by small steamers for about 100 m., and the Tsirihina is also navigable for a considerable distance. The former is about 300 m. long; the latter is much longer, but has its great rapids of little annoyance in the country, as also does the Mangoky. The rivers are all crossed frequently by rocky bars, which often form grand waterfalls. The eastern rivers cut their way through the ramparts of the high land by gorges of which the water is sometimes seen by the observation of rapids and cañonets. The Mântînàny, whose falls were first seen by the writer in 1876, descends at one place some 400 ft.; and on the Vôhîtra River, whose valley is followed by the railway, there are also many fine waterfalls.

On the eastern side of Madagascar the contest between the fresh water of the rivers and the sea has caused the formation of a chain of lagoons for nearly 300 m. in many of these places they look like a river flowing towards the sea. There are a number of extensive sheets of water. By cutting about 30 m. of canal to connect them, a continuous waterway could be formed for 270 m. along the coast. This has already been done for about 55 m. between IvoanbĤr and the mouth of the Tsirihina, an important part of the communication between the coast and the capital. Besides these lagoons, there are a few lakes of any size in Madagascar, although there were some very extensive lakes in a recent geological epoch. Of the largest of these, the Alôtra Lake in the Antsisrana plain is the relic; it is about 25 m. long. Next comes Kinkony, near Maroanbâtay Bay (N.W. coast), about 16 m. long, and then Itaky, in western Imérina, about half as large. There is also a salt lake, Tadràmbôta (S.W. coast), about as large as Alôtra.

There is now no active volcano in Madagascar, but a large number of extinct cones are found, some apparently of very recent formation. Some miles south of Dîgo-Suarez there is a huge volcanic mountain, Ambôbîhitra, which has signs of general activity and the subsidence of the volcanic region is indicated by the formation of the Onivô. About 40 m. south-west of Antânàrávîro there is a still larger extinct volcano, Ambôbîhitra, with an extensive lava field surrounding it; while near Lake Itaky there are some 200 volcanic cones. Around a number of extinct volcanoes is the Vakínàntàny district, S.W. of Ambôbîhitra. Many others exist in other parts of the island (see Geology). Slight shocks of earthquake are felt every year, and hot springs occur at many places. Several of these are sulphurous and medicinal and have been found efficient in skin diseases and in internal complaints.

**Geology.**—Madagascar may be divided into two very distinct geological regions, viz. (I.) the Archean Region, which extends over the central and eastern portions of the island and occupies about two-thirds of its whole area, and is composed of crystalline schists; and (II.) the Western Region, of sedimentary rocks, including the remaining third of the island, in the centre of which, however, is an isolated patch of Archean rocks, near Cape St. Andrew. There are also found in both regions numerous masses of igneous rocks, both of the first and second, and some places of the extent, which pierce through and overflow the earlier formations.
I. The Archean Region.—This region, nearly coincident with the mountainous upper portion of the island, is chiefly composed of the following crystalline rocks: gneiss, which is the most common of them all, quartzite and quartz-schist, with occasional beds of crystalline limestone and mica-schist, although this latter rock is very rare. The gneiss is mostly grey, but occasionally pinkish, its essential constituents (felspar and quartz) being almost always associated with dark mica (biotite) and hornblende in variable quantity. The rock is therefore a hornblende-granite-gneiss. Granite—more to S.S.W., but in its western portion the strike is frequently from N.N.W. to S.S.E. In both cases the strike of the rocks is coincident with the direction of several large valleys, which mark hard faults in the crystalline rocks. Almost the whole of this region is covered by red soil, often of great thickness, which resembles and is often described as “clay,” but which is decomposed rock, chiefly gneiss, reddened with oxidized magnetic.

II. The Sedimentary Region.—The sedimentary rocks extend continuously along the western side of Madagascar, following the coast-line; in the north these series of strata are only from 20 to 30 m. across, but farther south they reach a breadth of nearly 100 m., while opposite the Bétánily province they extend nearly half across the island. A narrow band, of Cretaceous age, occurs also on the east coast, for about 120 m., between Vatamandry and Mananjary. The following formations are represented:

1. Primary. It is thought that certain beds of slaty rocks, which have been recognized at different places, may belong to some of the Primary strata. Some siliceous schists of the Permian age were discovered in the valley of the Sakaméria, south of the Oniláhy, or Augustine river (S.W. coast). These contain reptilian remains, and also clear imprints of leaves of the Glossopteris indica, as well as other indications of an ancient vegetation. In the same region conglomerates have been found containing enormous blocks, apparently brought by glacial action, and said to be identical in character with those described as existing in the Transvaal. True coal has also been obtained in the same district, the deposits varying from a third to half a metre in thickness.

2. Secondary. The lowest members of these rest directly upon the central mass of crystalline rocks, and consist of sandstones, conglomerates and shales, which have been supposed by some to belong to the Trias, without, however, the discovery of any fossil necessary to this supposition, except some silicified trunks of trees. These beds are probably lower members of the Jurassic series. Westward of and above these strata, the Middle and Upper Jurassic formations are found (Lias, Lower Oolite, Oxfordian, &c.), with well-marked and numerous fossils (Ammonoïdes, Nautilus, Natica, Asterie, Rhyconochæa, Rickettias, &c.); but the Jurassic series, both these and the Jurassic series being largely developed, the Cretaceous fossils including Nautilus, Belénites, Ostrea, Gryphaea, &c., and some very common Ammonites (Pachychæa). The Secondary strata show generally a very slight dip westwards and are consequently almost horizontal. They do not seem to have been greatly disturbed, although faults occur here and there.

3. Tertiary. A small strip of coast of Eocene age is known near Tulluar (S.W. coast), and rocks of the same period occur in Nosibé, at Mahajamba Bay, and at Diégo-Suarez and Mananjary, and Nummulites and other foraminifers. Near the latter locality, beds of Oligocene age have been noticed, consisting of coarse limestones.

4. Quaternary and Recent. A narrow band of these deposits extends along the west coast, from north of Cape St Andrew nearly to the extreme southern point of the island. But the most noticeable of these are those in the ancient bed of the Alaotra Lake, which formerly extended far northwards along the valley of the Mangoro; also those in the marshes of Antsirabe and of Ifanja, in the kôka valley (the grand valley of the capital), and also in the plain of Tsânâmpârhy in Bétélô, and especially the recent deposits of Ampasamitombo, north-west of Lake Tâya, discovered in 1902. These beds, rich in sub-fossil remains, have yielded important additions to our knowledge of the extinct fauna of the island. (See § Palaeontology.)

Igneous Rocks. 1. Plutonic rocks.—The ancient or plutonic igneous rocks (including granite, syenite, diorite, gabbro, porphyry, porphyrite, norite and rhyolite) appear at various points of the two previously described regions. In the Archean region the gneiss is very often found passing into granite, but certain igneous masses have a sufficiently distinct character. In the midst of the sedimentary region are two well-recognized masses of plutonic rocks, belonging to the syenites, sometimes quartziferous in structure. 2. Volcanic rocks.—Recent volcanic eruptive rocks (including rhyolite, trachyte, phonolite, andesite and basalt) have been also represented at a number of points through the several geological regions of the island. In

---

1In the apparent absence of any Cambrian formation above them, there is little doubt that these rocks are Archean, although this cannot be absolutely proved.
The Archean region these are very noticeable near Lake Itasy, in the massif of Ankaratra (an ancient volcano) and in Vakinsankaratra (at Betâfo, Antsirabô, &c.); while there are numerous outflows of dolerite rocks, probably formed along the faults on the eastern side of the island. The Basalt region, with the Antsirabe massif, the volcanic district being a band of country parallel with the east coast and spreading at its southern end into the interior, and another tract, whose centre is about 100 m. of the capital (see § Industries, &c.), are the only exceptions. The Magnetite, Copper has been found in various localities, as well as zinc, lead, nickle, antimony and manganese, but none of these metals has yet been discovered in sufficient quantities for profitable working. Iron, on the contrary, especially magnetite, is found abundantly and can for long been worked by the Malagasy with the simple appliances brought by their ancestors from their original home in the Far East. The principal seats of the native industry are on the edge of the upper forest, where charcoal is easily procured. The following precious stones are reported: corundum (rubies and sapphires), beryl, topaz, zircon, garnet, amazon-stone, tourmaline, in large crystals, and variously coloured quartz, also often found in crystals. Among the semi-precious stones, turquoise and amethyst are common, and garnet is plentiful, salt and sulphur in lime are also procured. On the north-west coast thin beds of lignite occur, and coal has been found in the valley of the Sakâmibra.

In the province of Toliara the island have revealed the existence, in a subsoil fossil, of the bones of numerous birds of the family Struthiidae. These have been arranged in twelve species, belonging to two genera, Aepyornis and Mullerornis, which vary from the smallest to the largest. Among the birds found there are the remains of many other birds, including a hawk, a darter, an ibis, and a stork (of which only the bones have been found, about two-thirds the size of the living South American species). Also the bones of carapace, &c., of gigantic tortoises, and the bones of a crocodile, now extinct on the coast and rivers, but still living in the two chief lakes; also the remains of a river-bog, of a species of swine, and of a slender-legged form of zebu-ox. Near the south-west coast the skull of a large lemuroid animal was discovered in 1895, much larger than that of any living lemur, the archaeo-lemuroid (Microchoerus Giganteus) discovered by Chapman in Madagascar lemuroid. Later still, in 1898, and subsequently, the bones of two other creatures of the same suborder have been discovered, one of them indicating an animal much larger than a man. These bones and teeth are contemporaneous with the earliest human inhabitants of Madagascar. The remains of two species of Edentata have been found, as well as those of several species of small Rodents, also of a Carnivore (Aëmopus), a larger variety of the species still living in the island.

In the deposits of a much more remote era than those already spoken of—the Jurassic—the bones of some enormous terrestrial lizards have been brought to light, belonging to the Dinosaurs of the genera Bothriopnosaurus and Titanosaurus, and to a Theropod of the genus Megalosaurus. In the beds of the Lower Oolite portion of the skull of a reptile resembling the Gavial, the Indian crocodile, has been discovered, and a new species called Stenosaurus has been founded. Since the French occupation (1895) considerable additions have been made to our knowledge of the fossil fauna of Madagascar from researches made both on the west and the east coast (Ampasatamba and in the interior; at Antsirabe), especially in the rich deposits near Tsarazâna (Ambâsamba), the usual north-east the Cap, Iasy. From these various localities the sub-fossil remains of thirteen or fourteen distinct species of Saurian (as they are generally called) have been discovered; and, so far as known, these species have been confined to Madagascar. The bones of a small species of Hyrachyus (as it has been called) have also been discovered in the same locality, and very similar remains have also been found, the teeth being very characteristic of the species. The bones of a large species of Leptodeura have also been described, and it is possible that these species belong to the same genus. The teeth of both these species are highly specialized, and the species curiously preserved (Chiroxyma madagascarensis), an allied form, is one of the most peculiar and fascinating animals known, forming a genus and family by itself. Its whole system is an extraordinary one. Some of its bones are covered with boring larvae which form its food. Other peculiar animals are twenty-three species of the Centolidae, a family of the Insectivora almost confined to Madagascar; while the Carnivora there are several small creatures belonging to the civets (Viveridz). The largest of these ferocious animals, also forming a genus and family by itself, is the Cryptoproctus ferox; it is a plantigrade animal, 3 ft. long, but very like an enormous weasel, and attacks other animals with great ferocity. The island contains twenty-five species of bats, mostly of African, but some of Indian, affinities. African humped cattle were introduced several hundred years ago and now exist in large herds all over the country. The fan-tailed sheep, goats and rams have also been naturalized, as well as all kinds of domestic poultry.

The avi-fauna is much richer than the mammalian, and, although wanting the largest birds as well as the most brilliantly colored, among them many of the most remarkable birds of Africa. In the Malagasy, the majority of the birds of Madagascar, and probably, the most peculiar and distinctive. Many of the birds are remarkable not so much for their shape or colour as for their distant relationships; many belong to peculiar genera, and some are so isolated that new families have had to be formed for them. There are many typical birds, including several species of brilliant plumage—sun-birds, kingfishers, rollers, and flycatchers, &c.; kites, hawks and owls are numerous, and the lakes and marshes abound with water-fowl and herons. Among the most conspicuous of the Malagasy are the orioles, Acridotheres, Digitalis, &c., which are very common and are said to have been domesticated by the Malagasy for the sake of their sweet songs.

The island is free from deadly serpents, but contains two or three

1 For most of the information here given on the geology the writer is indebted to Captain Mouneyres, chief des services des mines, and the Rev. R. Baron, F.G.S., F.L.S.

3 The following are figures of mean temperature, kindly supplied by the Rev. E. Collins, S. J., the Rev. M. Garis, D. J., Diego Suarez, N., 79°; Fârâfângâna, S.E. coast, 75°; Moulovôy, W., 75°, 181°; Môronivôra, W. coast, 77°; Tullêrâ, S.W. coast, 78°.
small species of boa; crocodiles abound in the rivers and lakes; and
numerous species of lizard, chameleon and tree-frog inhabit the
woods. Madagascar may be considered as one of the headquarters
of the Chameleons, for of the fifty known species no fewer than
twenty live in Madagascar. In the two species from the eastern
departments these are of curious form, with remarkable developments of the
plates of the head and projecting horns and spines. There are
several peculiar tortoises, but the gigantic species are now
found alive only in two isolated groups, and the last one of these
life comprises many brilliantly-coloured beetles, butterflies (about
eight hundred species of which are known), moths, locusts, spiders
and flies, and also noxious spiders, with scorpions and centipedes.
The brightly-hued plants, of which there are countless varieties,
are of brilliant and bizarre appearance, with strongly con-
trasted colours in bands and spots. Those found in the coast waters
do not differ materially from the widely spread Indian Ocean species.
As Madagascan farmers are still largely carried away by
superstition, which would appear to be the result of long isolation from
the other zoological “regions.” The Asiatic and Malay characteristics of
many of its animals, as well as the physical conditions of the bed of
the Madagascar flora, make it highly probable that Madagascar,
while once forming part of Africa, is the chief relic of a considerable
archipelago formerly connecting that continent with Asia; its other
portions being shown by groups of small islands, and by coral atolls
and shoals, which are gradually disappearing. The islands of the full
range of life, according to Dr. A. R. Wallace in his
Geographical Distribution of Animals (vol. 1 ch. ix., 1876) and
Island Life, ch. xix. (1880).

Flora. The flora of Madagascar is one of great interest. One of
its most prominent features is the belt of forest round a large part
of the island at no great distance from the sea, and generally following
the coast-line. This forest is densest on the east side, and for about
120 m. forms a double line, the lower one being much the broader
and more important, and the other consisting of a broken line of
islands on the north-east, near Antongil Bay. The vegetation on the west
side of the island is much less dense, often appearing as scattered
clumps of trees on savannah-like plains rather than continuous
forest; while in the south-west, where the rainfall is least, the
vegetation is largely of flesh-leaved and spiny plants—aloe and
cacti (the latter introduced), with several species of Euphoria,
as well as numerous lianas, one of which (Intisy) yields India-rubber.
It is now known that the forest vegetation is almost entirely
composed of woody genera, which are absolutely different from those
in country in Madagascar, or about one-eighth of its whole surface.
The vegetation of the forests, the abundant epiphytes, the
mosses, the filmy ferns and the viviparous character of many of the
fern species, and the climbing lianas, are among the diagnostic
features of this region. This contains a large variety of hard-wooded and valuable
bark trees, including species of Weinmannia (Laïnon), Ela-eocarpus
(Volanoa), Dalbergia (Yoamôna), Nuxia (Yânamôna), Pedocarpus,
a pine, the sole species in the island (Helitala), Tamarindus (Ambôro),
Neobocrates (Hârâhârë), Ocesta (Yamandura) and probably many others.
Diospyros sp., &c. The following trees are characteristic of
Madagascar vegetation, some of them being endemic, and others very
prominent among the local land-plants: Mimosae, Hovea (Hovea
speciosa), with its graceful crown of plantain-like leaves growing
like an enormous fan at the top of a tall trunk; and affording a supply
of pure cool water, every part of the tree being of service in building
structures (Mada-Hovæ), parallel with the use of this tree by the
Casuarina equisetifolia or beef wood tree, very prominent on the
eastern coast, as well as several species of screw-pine (Pandanus);
the Madagascan spice (Ravinsâra madagascariensis), a large forest
tree; the screw-ash (from France, Claricea), the Madagascar
calophyllum; and the Têngâna (Tângnigna venënsifia), formerly
employed as an ordeal. On the lagoons and lower reaches of
the rivers the Viha (Typhonondorum lindleyanum), an arum endemic
to Madagascar, grows in great profusion to a height of 15 ft.,
and has a white spathe more than a foot long; and on the
western coast dense thickets of mangrove line the creeks and rivers.
In the interior rivers is found the curious and beautiful lace-leaf
tree, Nymphaea (Nymphe), and a tree next related to it, the
 마고시, the western side of the island the baobab, the tamarind, the rôta
(Eugenia sp.), the rofa palm, and several species of fan-palm
(Hyphaeae) and of Ficus are prominent; and the mango (introduced
into the island) is abundant. In the highlands, larger trees,
species of Ficus (Acomâla, Avâvey, Nômoko, Addô, &c.), often
mark the position of the old towns; and some of these,
the ambôhîmanga, Vôhilena, &c., are surrounded by remains of the
original forest, and marked by the appearance of the forest floors.
The most prominent tree in the central province is now the Câpe-
lâîca (Melia aserodoch) introduced about 1825; and since the French
conquest several species of eucalyptus have been planted in vast
numbers, especially around the capital, Antananarivo, and to the
vegetation, while bright colour is imparted by species of
Bougainvillea and Poinsettia. In the eastern forests palms, bamboos,
lianas and tree-ferns, as well as species of Dracaena, are found.

Among flowers growing on the ground or on shrubs are not
conspicuous for number or beauty, there are many fine flowering
flowers, such as Poinciana regia, presenting a mass of scarlet flowers;
Cobûlisa racemosa, with yellow flowers; Astrâcepes Wallichii, striking
attention from its abundant flowers; and species of Cryptostegia, a
purple-flowered creeper, and Strongylophod, another creeper with
cream-coloured blossoms. Among attractive plants are species
of Philodendron; Nenia, Commelina, Cleome, &c. On the
east coast two orchids, species of Angraecum, with large white
large flowers, one with an extraordinarily long spur or nectary,
the attract the attention of every traveller during June and July by
the beauty and fragrance of their blossoms; the forest fronds are
large, and there are large numbers of spiny and prickly plants,
as well as numerous grasses, reeds and rushes, many of
them of great service in the native manufactures of mats, hats, baskets, &c.

The Rev. R. H. Williamson divides the floras into three distinctively marked
regions, which run in a longitudinal direction, following approximately
the central line of the island from the north to the south. The
rivers, the forests, the plantations, the villages and the
coastal settlements are the products of this region. The
four hundred known plants—of which about three-fourths are endemic
and growing in the Madagascar flora, there are 3400 Dicroleneae,
248 Monocotyledons and 350 Acotyledons. Of these, the orders most
largely represented (together with their species) are: Leguminosae, 346;
Ficiles, 318; Compositae, 281; Euphorbiaeaceae, 228; Orchideae,
176; Cynips, 160; Rubiaceae, 147; Acanthaceae, 131; Gramineae, 120.
The number of species native to Madagascar is 1,243; 1,283 of
the 3,718 species of plants whose localities have been determined, 35% of
are peculiar to the eastern region, 27.5% to the central, and 22% to the
western. In other words, 42% of the total number of species are
endemic. In the central region there is a type of vegetation which is
distinctly confined to Madagascar. A number of species are
widespread in Africa, but not Madagascar; and the flora of the mountains corresponds closely with
that of the great ranges of the tropical zone of Africa. The
general plan of the floras follows the same lines as that of the
vegetation of the central and eastern parts of the island. The introduction of new species
is very slow, and the flora of Madagascar is remarkably stable.

Among the food-giving plants are the rice, the root crops, the
of the Malagasy—a mere catalogue of species, such as rice, beans, &c.
are grown, including ginger, capsicum, &c.; sugar-cane, coffee, indigo,
vainilla, tobacco, cotton, hemp, gourds, dye-woods, gums, mulberry
and other trees and plants for silk-culture, are all among the vege-
table products of Madagascar. The forest is of great importance as
a source of timber for the country, and India-rubber is still,
an important article of export.

Provinces and Towns.—The island may be divided into dis-
tricts or provinces, which in the main indicate tribal divisions.
Among these tribal territories the following may be distinguished,
taking them in three main divisions, from north to south:
(1) Eastern: Antankâranâ, the northern peninsula; the
country of the Bétimisârâka, who inhabit a large extent of the
coast plains, about 500 m. in length; parallel with this for
about a third of it, and between the two lines of forest, is the
Béazâna country. South again are the districts of the
Tambahâoaka, the Taimôrâ, the Taîlîsâ and the Taîsâkâ; and
the south-eastern corner is the Tanôsâ. (2) Central: the
districts of Tsimihetâ and the Sihânâka; Iméridâ, the Hova
province; the Bêtisî; the Tanâla or forests; the Bârâ;
and the emigrant Tanôsî. (3) Western: the people from
the coast, the southern parts of the island; the Sakâmbo
aried out of number of distinct
tribes—the Tôbinâ, the Mâlîkâ, the Tanôsî and the
Fiberâna, &c. South of these last are the Mâhâfâl, with the
Tandrî at the extreme south. There are no distinctly marked
boundaries between any of these tribal territories; and
west of Iméridâ and Bêtisî there is a considerable extent of country with hardly any population, a kind of
“no-man’s-land.” There are numerous subdivisions of most of the

The capital, Antananarivo (pop. 69,000), is the capital of the
highlands of Iméridâ, and Tamarâ, or Tapâ (pop. 4600), on the
east coast and the chief seaport, are separately described. Majunga (properly
Mohâ, pop. 5300) on the north-west coast, just north of
6° S., and Diego-Suarez, are important ports for foreign trade,
the latter being also a fortified naval and military station.

Other ports and towns are Mâhânôrâ, Mânjâny (S.E. coast,
pop. 4500), Tulear (S.W. coast), and fianarántsoa
(pop. 6200), the chief town of the Bêtisî. There are very
few places besides these with as many as 2000 people.

The words in parentheses are the native Malagasy names.
MADAGASCAR

Inhabitants. — The population is somewhat under two and three-quarter millions, including some 10,000 or 11,000 Europeans, and a smaller number of Indian, Arab, and other Asians, mostly small traders found in the seaports, the Chinese being found in every town of any size. The island, it will be seen, is very sparsely inhabited; the most densely peopled province is that of Iména with (1905) 388,000 inhabitants. The natives, collectively known as Malagasy, are divided into a considerable number of tribes, each having its distinct customs. Although geographically an African island, the majority of its inhabitants are derived, the lighter portion of them from the Malayo-Polynesian stock, and the darker races from the Melanesians. This is inferred from their similarity to the peoples of the Indian and Pacific archipelagoes in their physical appearance, mental habits, customs, and, above all, in their language. Their traditions also point in the same direction. There is, however, an undoubted African mixture in the western and some other tribes. There is also an Arab element both on the north-west and south-east coasts; and it appears that most of the families of the ruling classes in all parts of the island are descended from Arabs, who married native women. It is believed that there are traces of an aboriginal people (the Vazimba), who occupied portions of the interior before the advent of the present inhabitants, and these appear to have been a somewhat dwarfish race, and lighter-coloured than the Malagasy generally. The Hôvà became the dominant tribe from the beginning of the 19th century; they appear to be the latest immigrants, and are the lightest in colour; and they are also the most intelligent and civilized of all the peoples inhabiting the island.

The most striking proof of the virtual unity of the inhabitants of Madagascar is that substantially but one language is spoken over the whole country. The Malayo-Malagasy language, which we noted in the 16th century; indeed, the second and fifth books published upon the country (in 1603 and 1613) were comparative vocabularies of these two languages. Later investigations have confirmed the conclusions thus early arrived at; and Van der Tuuk, Marie de Marin and W. E. Cousins have shown conclusively the close relationships between the language of the Malagasy and those of the Malayo-Polynesian regions; similar connections exist, especially in grammatical construction, between the Malagasy and Melanesian languages. The Malagasy had never invented for themselves a written character, and had consequently no manuscripts, inscriptions or books, until their language was reduced to writing, and its orthography settled by English missionaries. Their speech nevertheless is very full in many of its verbal and other forms, while it also exhibits some curious deficiencies. It is very soft and musical, full of vowels and diphthongs, and free from all harsh gutturals. Native oratory abounds in figures, metaphors and parables; and a large number of folk-tales, songs and legends, together with the very extensive proverbs, give ample evidence of the mental ability and imaginative powers of the Malagasy.

NATIVE SOCIETY IN IMÉNA. Among the Hôvà the society was divided into three great classes: the Andriana, or nobles; the Hôva, freemen or commoners; and the Andêvo, or slaves; but these last became free by a proclamation issued in 1896. The Andriana are, strictly speaking, the chiefs and nobility, being descendants of the chiefs who, either through choice or otherwise lost their authority through the increasing power of the ancestors of the reigning family. Their descendants retained certain honours in virtue of their royal origin, such as special terms of salutation, the use of the smaller scarlet umbrella (the larger one was the mark of royal rank), the right to build a particular kind of tomb, &c.; they also enjoyed exemption from certain government service, and from some punishments for crime. The Hôva or commoners form the middle class; they are the population of Iména. They are composed of a large number of tribes, who usually intermarry strictly among themselves, as indeed do families, so that property and land may be kept together. The third great division was the slave population, which, since 1896 has become merged in the mass of the people. The Mozambiques or African slaves, who had been brought from the African coast by Arab shobs, were in 1877 formally set free by an agreement with the British government.

But the most important feature of the Hôva, as of all the other races of the island, is their close connexion with the islanders of the northern Pacific. The shutting of the Straits of Tiran, and the opening of the strait to the north of Madagascar, closed the way to the north, and the Hôva became isolated from the other races of the island, and were not in the slightest degree affected by foreign influence. The Hôva, or rather the Andriana, retained their old traditions, and adopted no European customs. The chiefs, in their high offices, all retained their old titles, and were worshipped as gods; in its modern development among the Hôva sovereigns it gathered round it much state and ceremony. There were many curious examples of the taboos with regard to actions which, in the case of royalty, were forbidden to all other races. The current belief of the people made it necessary to relate the Hôva sovereigns and their surroundings. These were particularly in evidence having to do with the burial of a monarch. While the foregone description of native society applied chiefly to the Hôvà, it equally applied to the other races of the island. But on the island becoming a French colony, in 1896, royalty was formally abolished; and little regard is paid to native rank by French officialdom.

The chief employment of the Malagasy is agriculture. In the cultivation of rice they show very great ingenuity. The ketau grounds, where the rice is sown before transplanting, being formed either on the shores of the lagoon, or in the swamps of the lagoon, by the cultivation of rice the whole year round, and the rice is rated on position. In preparing the rice for use it is pounded in a wooden mallet to remove the husk, this work being almost always done by the women. The manioc root is also largely consumed, together with several fruits and vegetables; but little animal food (save fish and freshwater crustacea) is eaten by the Malagasy, except at festival times. Rice is used less by the western tribes than by those of the central and eastern provinces, and the former people are more nomadic in their habits than the others. Large herds of fine-humped cattle are found almost all over the island.

The central and eastern peoples have considerable manual dexterity. The women spin and weave, and with the rudest appliances manufacture a variety of strong and durable cloths of silk, cotton and wool, and many of the costumes common to the Kwara-wara, Madiqua, and Betsileo, are of these fabrics, and often with much taste in colour. They also make from straw and papyrus peel strong and beautiful mats and baskets in great variety, some of much fineness and delicacy, and also hats resembling the panama, and with the same graceful brim. They make also large use of soft rush matting for covering, and also they prepare a rough cloth of bark. Their non-employment of skins for clothing is a marked distinction between the Malagasy and the South African peoples; and their use of cotton is further evidenced by the evidence of the annual large export of cotton for clothing, between them and the Polynesian peoples. The men wear a loin-cloth or salake, the women a kimba or a strip of cloth folded round the body from waist to heel, to which a jacket or dress is usually added; the women often wear, over a strip of cloth folded round the body something like the Roman toga, and which is the characteristic native dress. The Malagasy are skilful in metal-working; with a few rude-looking tools they manufacture silver chains and necklaces, and bracelets and rings of silver. Their iron-work is of excellent quality, and in copper and brass they can produce copies of anything made by Europeans. They display considerable inventive power, and they are exceedingly quick to adopt new ideas from Europe than the majority of their more remote neighbours.

There is a considerable variety in the houses of the different Malagasy tribes. The majority of Hôva houses were formerly built of layers of the hard red soil of the country, with high-pitched roofs thatched with grass or rush; while the chiefs and wealthy people build their houses of marble or chunks of marble. The houses are massive upright planking, and lofty covered with shingles or tiles. But the introduction of sun-dried and burnt bricks, and of roofing tiles in the central provinces has led to the general use of these materials in the building of houses, and they are now more numerous in the central provinces, and in those of the coast peoples are more cleanly and roomy. Among the Hôva and Betsileo the old villages were always built for security on the summits of lofty hills, around which were dug several deep fosses, one in the on the other. The houses stood on platforms and the roofs were covered with thatch. Instead of the natural materials are enclosed within formidable defences of prickly-pear or thorny mimosa.

Apart from the modern influence of religious teaching, the people are on the whole isolated. They are cut off from all intercourse of human life and suffering, and cruel in war. Until lately polygamy has been common among all the Malagasy tribes, and divorce effected in an absurdly easy fashion. At the same time the position of woman is much higher in Madagascar than in most heathen countries; and the fact that for nearly seventy years there were (with a few months'
exception) only female sovereigns, helped to give women considerable influence in native society. The southern and western peoples still practise infanticide as regards children born on several unlucky days in each month. This was formerly the general practice all over Madagascar, and it was said that there could be no forgiveness for those who would not become solemn in their punishments, and death in various cruel forms was inflicted for very trifling offences. Drunkenness is very prevalent in many parts of the island; and it can hardly be said of many of the Malagasy that intemperance is not a national vice. But there is not always recourse to their chiefs and tribe, and for short periods are capable of much strenuous exertion. They are affectionate and firm in their friendships, kind to their children and aged and infirm relatives, very respectful to old age, and in courteous and polite hospitalities to strangers. Slavery had a patriarchal and family character, and was seldom exercised in a cruel or oppressive way.

The Malagasy have never had any organized religious system or forms of worship; there are no temples, images or stated seasons of devotion. There is there a priesthood, properly so-called. Yet they have never been without some distinct recognition of a supreme being, whom they call Andranonon'ita, "The Fragrant One," and Zodahary, "The Creator"—words which are recognized all over the island. They have also retained many ancient sayings, proverbs in their style, which enforce many of the truths of natural religion as to the attributes of God. With all this, however, there has long existed a kind of idolatry, which in its origin is simply fetishism—the belief in columns of sucking and breathing beings and protection from certain evils. Among the Hova in modern times four or five of these charms had acquired special sanctity and were each honoured as a kind of national deity, being called "god," and brought out on certain occasions. This belief is still modernly a firm belief in the power of witchcraft and sorcery, in divination, in lucky and unlucky days and times, in ancestor worship, especially of the sovereign predecessors, and in several curious orders of amulets. But the modern known superstitions are not the old venerated tabu; the old venerated tabu are the dreaded tanga poison ordeal, in which there was implicit belief, and by which, until its prohibition by an article in the Anglo-Malagasy treaty of 1861, thousands of persons perished every year. Sacrifices of oxen and other animals and many flowers and plants were then offered at the altars, both in thanksgiving at times of harvest, &c., and as propitiatory offerings. Blood and fat are used to anoint many of these stones, as well as the tombs of ancestors, and especially those of the sovereigns of the past; and it is said that among all the tribes who have sacred stones and altars, that the sacrifice of human blood were occasionally offered. The chief festival among the Hova, and almost confined to them, was that of the Novee, at which time a kind of sacred killing of oxen took place, and a ceremonial bathing from which the festival took its name of Fándraona (the Bath). This festival is now merged in the French national fête of the 14th of July. Another great festival was at circumcision times. This rite was observed by royal command at intervals of a few years; these were occasions of great rejoicing, but also of much drunkenness and licentiousness. Since 1868 circumcision has been observed by each family at any time convenient to itself. It is practised by all the Malagasy tribes. Funerals were also times of much feasting, and at the death of people of wealth they were often not allowed to be kill. Although there was no proper priesthood, the idol-keepers, the divers, the day-declagers and some others formed a class of people closely connected with heathen customs and interested in their continued observance.

Industries and Commerce.—The rearing of cattle and the dressing of hides, the collection of rubber and bee culture are important industries. The chief food crops grown have been indicated (see Flora), and the gold-mining is separately noticed below. Other industries undertaken or developed by Europeans are tobacco, cotton, tobacco-leaf, hemp and rice-growing. There has been ostrich farming. Sugar, rice, soap and other factories have been established. In 1904 the exportation of straw and other fibre hats began; these resemble those of Panama and promise to become an important item. Tanning bark, coffee and guano are also recent exports.

Since 1862, when the country was thrown open to foreign trade, the growth of over-sea commerce has been comparatively slow. In the early days cattle were the chief export. About 1850 India-rubber began to be considered in considerable quantities, and cattle, rubber and hides continue staple products. Other important exports are raphia fibre and beeswax. Since 1900 gold has become a leading export, the value of the gold sent out of the country in the five years 1901-1906 being £1,384,493. The imports consist chiefly of tissues (mostly cotton goods), breadstuffs and rice, liquors, metal-wage and coal. Better means of internal transport and increased production in the island have greatly reduced the import of rice, which came mostly from Saigon.
of a community; at its head is a chief or mpandadi, who serves for three years.

For Europeans and in suits between Europeans and natives the French judicial code is applicable; suits between natives are tried by native tribunals (established 1898) presided over by a European assisted by two native assessors. These tribunals judge according to native law and usage, except where such customs (e.g., marriage and slavery) have been expressly abolished. Arbitration councils are available everywhere for the settlement of disputes between native workmen and their employers. The native laws respecting land have been improved by the adoption of a method of registration based on the Torrens system.

Revenue is derived from land, house and capitation taxes, from customs, posts and telegraphs, ferries, licences and other indirect imports. The chief revenue is derived from customs duties and imposts. A considerable portion of the revenue is expended on public works. Revenue and expenditure in 1905 were each just beneath £1,000,000. This is exclusive of the sums spent by France on the island as the army, and for the naval base at Diego-Suarez. There is a public debt amounting (1907) to £4,055,600. As stated in the French senate (February 1900), everything is taxed in the island; and no sooner has any enterprise become fairly successful than it is so heavily taxed as to be no longer profitable. The expenditure is largely due to the wars and to subventions from France. The island is maintained at much the same cost as Madagascar, and it is an unprofitable item in the accounts of the French government, and the demand is constantly increasing.

History.—From the earliest accounts given of the people of Madagascar by European travellers, as well as from what may be inferred from their present condition, they seem for many centuries to have been divided into a number of tribes, often separated from one another by a wide extent of uninhabited country. Each of these was under its own chief, and was often at war with its neighbours. No one tribe seems to have gained any great ascendancy over the rest until about the middle of the 17th century, when a small but warlike people called Sakalava, in the south-west of Madagascar, advanced northward, conquered all the inhabitants of the western half of the island, as well as some northern and central tribes, and eventually founded two kingdoms which retained their supremacy until the close of the 18th century. About that time, the Hova in the central province of Imérima began to assert their own power under two warlike and energetic chieftains, Andrianimpoina and his son Radama; they threw off the Sakalava authority, and after several wars obtained a nominal allegiance from them; they also conquered the surrounding tribes, and so made themselves virtual kings of Madagascar. From that time until 1845 Hova authority was retained over a large part of the central and eastern provinces, but it was only nominal over much of the western side of the island, while in the south-west the people were quite independent and governed by their own chiefs.

While European intercourse with Madagascar is comparatively recent, the connexion of the Arabs with the island dates from a very remote epoch; and in very early times settlements were formed both on the north-west and south-east coasts. In the latter locality there are still traces of their influence in the knowledge of Arabic possessed by a few of the people. But in these provinces they have become merged in the general mass of the people. It is different, however, in the north-west and west of the island. Here the Arab element, much more than on the eastern coast, has been the stronger, largely due to the number of captives and slaves who were captured from the islanders by the Arabs. The name of the island, Arabia, is said to be derived from a town on the coast of Arabia, and nostra from one on the coast of Basutoland. The predominance of superstition was greatly broken, a result partly due to the keen good sense of the king, but chiefly to the spread of knowledge and religious teaching.

The bright prospects thus opening up were clouded by the death of Radama I. (1810–1828). He was a man much in advance of his age—shrewd, enterprising, and undeterred by difficulty—a kind of Peter the Great who ended his time. He saw that it was necessary for his people to be educated and civilized if the country was to progress; and making a treaty with the governor of Mauritius to abolish the export of slaves, he received every year in compensation a subsidy of arms, ammunition, and uniforms, as well as English training for his troops. He was thus enabled to establish his authority over a large portion of the island. For some years a British agent, Mr Hastie, resided at Radama's court, and exercised a powerful influence over the king, doing much for the material advance of the country. At the same period (1820) Christian teaching was commenced in the capital by the London Missionary Society, and by its missionaries the language was reduced to a systematic written form, and the art of printing introduced; books were prepared, the Scriptures were translated, numerous schools were formed, and several Christian congregations were gathered together. The knowledge of many of the useful arts was also imparted, and many valuable natural productions were discovered. The power of superstition was greatly broken, a result partly due to the keen good sense of the king, but chiefly to the spread of knowledge and religious teaching.

The bright prospects thus opening up were clouded by the death of Radama I. at the age of thirty-six, and the seizure of the royal authority by one of his wives, the Princess Rànavàlona. She looked with much suspicion upon the ideas then gaining power among many of her people, and determined to strike a decisive blow at the new teaching. In 1835 the profession of the Christian religion was declared illegal; all worship was to cease, and all religious books were ordered to be given up. By the middle of 1836 all the English missionaries were obliged to leave the island, and for twenty-five years the most strenuous efforts were made by

MADAGASCAR

The island is mentioned by several of the early Arabic writers and geographers, but medieval maps show curious ignorance of its size and position. Marco Polo has a chapter upon it, and terms it "Madageisar," but his accounts are confused with those of the mainland of Africa. The first European voyager who saw Madagascar was a Portuguese named Diogo Dias, captain of one of the ships of a fleet commanded by Pedro Cabral and bound for India. Separated from his companions by a storm near the Cape, he sighted the eastern coast of the island on the 10th of August 1500. That day being the feast of St Lawrence, Madagascar was named the "Isle of St Lawrence," and retained that name on all maps and charts for a hundred years. The Portuguese gave names to most of the caps, but made no persistent attempts at colonization. After them the Dutch endeavoured, but with little success, to form colonies; and in the time of Charles I. proposals were made to form an English "plantation," but these were never carried into effect, although for a short time there was a settlement formed on the south-west coast. In the latter part of the 17th and during most of the 18th century the French attempted to establish military posts on the island. At times they held the extreme south-east point of the island at Fort Dauphin; but several of their commandants were so incapable and tyrannical that they were frequently involved in war with the people, and more than once their stations were destroyed and the French were massacred. Early in the 19th century all their positions on the mainland were relinquished, and they retained nothing but the island of Ste Marie on the east coast. In 1811 Tamatave had been occupied by British troops, and the Treaty of Paris of 1814 recognized as British the "French settlements in Madagascar," but as a matter of fact France had then no settlements on the mainland. The then governor of Mauritius, Sir Robert Farquhar, endeavoured to prosecute British claims and obtained a cession of Diego-Suarez Bay. These claims were not backed up by the home government, and a little later the policy was adopted by Great Britain of supporting the Hova authority.

The political history of Madagascar as a whole may be said to date from the reign of Radama I. (1810–1828). He was a man much in advance of his age—shrewd, enterprising, and undeterred by difficulty—a kind of Peter the Great who ended his time. He saw that it was necessary for his people to be educated and civilized if the country was to progress; and making a treaty with the governor of Mauritius to abolish the export of slaves, he received every year in compensation a subsidy of arms, ammunition, and uniforms, as well as English training for his troops. He was thus enabled to establish his authority over a large portion of the island. For some years a British agent, Mr Hastie, resided at Radama’s court, and exercised a powerful influence over the king, doing much for the material advance of the country. At the same period (1820) Christian teaching was commenced in the capital by the London Missionary Society, and by its missionaries the language was reduced to a systematic written form, and the art of printing introduced; books were prepared, the Scriptures were translated, numerous schools were formed, and several Christian congregations were gathered together. The knowledge of many of the useful arts was also imparted, and many valuable natural productions were discovered. The power of superstition was greatly broken, a result partly due to the keen good sense of the king, but chiefly to the spread of knowledge and religious teaching.

The bright prospects thus opening up were clouded by the death of Radama I. at the age of thirty-six, and the seizure of the royal authority by one of his wives, the Princess Rànavàlona. She looked with much suspicion upon the ideas then gaining power among many of her people, and determined to strike a decisive blow at the new teaching. In 1835 the profession of the Christian religion was declared illegal; all worship was to cease, and all religious books were ordered to be given up. By the middle of 1836 all the English missionaries were obliged to leave the island, and for twenty-five years the most strenuous efforts were made by
the queen and her government to suppress all opposition to her commands. This, however, only served to show in a very remarkable manner the courage and faith of the Christian Malagasy, of whom about two hundred suffered death in various cruel forms, while many hundreds were punished more or less severely by fine, degradation, imprisonment and slavery. During the queen's reign the political condition of the country was deplorable; there were frequent rebellions, many of the distant provinces were desolated by barbarous wars; and for some years all Europeans were excluded, and foreign commerce almost ceased. This last circumstance was partly owing to an ill-managed attack upon Tamatave in 1846 by a combined British and French force, made to redress the wrongs inflicted upon the foreign traders of that port. But for the leave of Christianity and education which had been introduced into the country it would have reverted to a state of barbarism.

This reign of terror was brought to a close in 1861 by the death of the queen and the accession of her son Radama II. The island was reopened to European trade, and missionary efforts were recommenced. A determined attempt was made by some Frenchmen to gain for their country an overwhelming influence by means of a treaty which they induced the king to sign. But this act, as well as the vices and insane follies into which he was led by worthless foreign and native favourites, soon brought his reign and his life to an end. He was put to death in his palace (1863) and his wife was placed on the throne. The new sovereign and her government refused to ratify the agreement which had been illegally obtained, choosing rather to pay a million francs as compensation to the French company. During the five years' reign of Queen Rasohérina, quiet and steady advances were made in civilization and education, and treaties were concluded with the British, French and American governments.

At the death of Rasohérina in 1868, she was succeeded by her cousin, Ranaváloana II. One of the first acts of the new queen was the marriage of her son, and very soon afterwards she and her husband, the prime minister, were baptized, and the erection of a chapel royal was commenced in the palace yard. These acts were followed in the succeeding year by the burning of the royal idols, and immediately afterwards by the destruction of the idols throughout the central provinces, the people generally putting themselves under Christian instruction. From that time education and enlightenment made great progress, chiefly through the labours of missionaries of various societies.

The native Malagasy government, though theoretically despotic, was limited in various ways. Radama I. and Ranaváloana I. were much more absolute sovereigns than those before or after them, but even they were largely restrained by public opinion. New laws were announced at large assemblies of the people, whose consent was asked, and always given through the headmen of the different divisions of nationality; the common was no longer a dividing wall from a time when the popular assent was not a merely formal act. The large disciplined army formed by Radama I. aided much in changing what was formerly a somewhat limited monarchy into an absolute one. The Hova queen's authority was maintained over the central and eastern portions of Madagascar, and at almost all the ports, by governors appointed by the queen, and supported by small garrisons of Hova troops. At the same time the chiefs of the various tribes were left in possession of a good deal of their former honours and influence. Ranaváloana II., her predecessor and her successor were successively married to the prime minister, Raminilalàivony, a man of great ability and sagacity, who, by his position as husband and chief adviser of the sovereign, became virtual ruler of the country. Chiefly owing to his influence, many measures tending to improve the administration were introduced. The Hova army was estimated at from 30,000 to 40,000 men, several English non-commissioned officers and, latterly, others of higher rank being engaged to train them in European methods. Revenue was derived from customs duties, firstfruits, fines and confiscation of offenders' property, and a money offering called hivina, presented on a great variety of occasions both to the sovereign in person and to her representatives; and these were supplemented by "benevolences" (in the medieval sense of the word) levied upon the people for occasional state necessities. The government also claimed the unpaid service of all classes of the community for every kind of public work.

The Hova government aspired to have Madagascar recognized as an independent civilized state, and consuls appointed by the British, French and American governments were accredited to the Malagasy sovereign, the queen having a consul in England, and a consular agent at Mauritius. The treaty with Great Britain, concluded in 1865, gave the consuls of that nation jurisdiction over the British subjects in the island. At this period, on the initiative of the 4th earl of Clarendon, then foreign secretary, an understanding was come to between the British and French governments by which it was agreed that each power should respect the independence of Madagascar; and the future of the country appeared to be bound up in the gradual consolidation of the central Hova authority over the whole island. While this prospect would have satisfied the British interests in the island, it was otherwise with the French. The tradition of their former settlements in and influence over the island was strong; in 1840 they had taken under their protection the Sákalávà ruler of the small island of Nossi-bé, off the north-west coast, and in virtue of that act claimed a vague protectorate over the adjacent shores of the mainland. A treaty, concluded in 1868, while establishing French consular jurisdiction in Madagascar, recognized Ranaváloana II. as queen of Madagascar, and under the Second Empire attempts to establish French political influence were discouraged, and even as late as 1872 the subsidy enjoyed by the Jesuit missionaries was withdrawn. In 1878 the French consul, Laborde, died, and a dispute arose as to the disposal of his property. This dispute was the occasion of further intervention on the part of the French, for the Paris government supported the claims of Laborde's heirs, and revived their claim to a protectorate over the Sákalávà of the north-west coast, as based on their agreement with them in 1840, ceding Nossi-bé to France. A policy of colonial expansion generally, and in Africa in particular at this time, was manifest in France, as in other European countries, and the French claims on the Hova were pressed with vigour.

Towards the middle of 1882 the relations between the native government and that of France became much strained, and to settle, if possible, these causes of dispute, two Hova officers of high rank were sent to France as ambassadors, but as they were not authorized to concede any territory, their visit accomplished very little. Treaties had been concluded with Great Britain, Germany and America, giving improved facilities for trade with Madagascar, but before the return of the envoys matters had become so serious that the Hova government, in May 1883, an ultimatum was put to the Malagasy queen, requiring immediate compliance with the demands of France; and as these were refused by the Hova government, Tamatave was bombarded by a French squadron and then occupied by the marines. The war continued in a desultory fashion for many months; but no serious attempt was made to invade the interior; and in 1885 terms of peace were agreed to. By a treaty signed on the 17th of December it was agreed that the foreign relations of Madagascar should be directed by France; that a resident should live at the capital, with a small guard of French soldiers; and that the Bay of Diégo-Suarez, together with surrounding territory, should be ceded to France. The word "protectorate" was carefully excluded from the treaty, although doubtless the French envoys intended that this should be its practical issue. It was at the same time agreed that there should be no foreign interference with the internal government of the country, and that the queen should retain her former position, with all its honours and dignity. It should be here noticed that the queen, Ranaváloana II., died just at the beginning of the war, on the
13th of July 1884, and was succeeded by her niece, Princess Razàndrahety, under the title of Rànavalana III, who, in return for concessions in Zanzibar, had consented, in 1890, to recognize a French protectorate over Madagascar, the Malagasy prime minister, Rànililàiarivosy, was not disposed to give any advantage to France and continued to arm and train, by the help of British officers, a large body of native soldiers. This state of tension and irritation could not last, and at length, towards the close of 1894, the French government sent an ultimatum to the Malagasy sovereign, demanding such powers as would have made French authority supreme in the island. These demands were refused by the native government, and other conditions were offered; but the French envoy, together with the resident's escort, left the capital, as also did several French residents successively represented France at Antananà-ràiso, 1855-1894. These findings have enabled us to observe that influence which the home authorities thought they had a right to demand. Although the British government, in return for concessions in Zanzibar, had consented, in 1890, to recognize a French protectorate over Madagascar, the Malagasy prime minister, Rà-nililàiarivosy, was not disposed to give any advantage to France and continued to arm and train, by the help of British officers, a large body of native soldiers. This state of tension and irritation could not last, and at length, towards the close of 1894, the French government sent an ultimatum to the Malagasy sovereign, demanding such powers as would have made French authority supreme in the island. These demands were refused by the native government, and other conditions were offered; but the French envoy, together with the resident's escort, left the capital, as also did several French residents successively represented France at Antananà-ràiso, 1855-1894.

French invasion and the French traders and others, including the large Jesuit mission. As soon as these had left the island, the chief ports were occupied by French troops, and an expeditionary force under General Duchesne was afterwards landed on the north-west coast at Mâjanga—commonly, but incorrectly, written Majunga—with the object of breaking the Hôva authority. Owing to the necessity of making a road for the passage of artillery and military stores, many months were spent on the march into the interior, and there was considerable loss of life by fever and other disease among the invading troops. But no effectual resistance was made by the Malagasy, and at length, on the 30th of September 1895, the French forces appeared on the heights north and east of Antananà-ràiso, bombarded the city, which surrendered in the afternoon, and on the evening of the same day the French entered the capital.

The result was that the protectorate of France was re-established in the central provinces, but the queen was allowed to retain her position. Early in 1896, however, a serious rebellion broke out in several parts of Iméria. This movement was not only anti-French and anti-foreign, but also distinctly anti-Christian. The French troops gradually broke up the power of the rebellion in the central provinces, but as there appeared to be considerable unrest in many other parts of the island, General Gallieni, an officer with a reputation for vigour and ability in the Sudan and Tongking campaigns, was sent out to relieve the then resident-general.

General Gallieni had a difficult task in establishing the authority of France throughout the island among numbers of tribes who had never submitted to any control from others. Among the first steps he took were to put the country under martial law, to abolish royalty and all semblance of Hôva government, and to declare Madagascar to be henceforth a colony of France. Queen Rànavalana III. was exiled to Reuion, and subsequently to Algeria. Meanwhile carriage roads were commenced to connect all the chief centres, and the military posts were gradually extended so as to consolidate French rule over all the outlying tribes. French residents and numerous other officials were placed at every important town, and various projects were started for the civilization of the Malagasy in accordance with French ideas. At the close of 1895, General Gallieni was able to report that only portions of the east and south-west remained to be brought into submission, but after the French army had been reconnoitered throughout the island, General Gallieni, whose firm and vigorous administration, and desire to treat the Malagasy justly and kindly, made him liked by the people, retired in 1903, and was succeeded in that office by M. Victor Augagneur, late mayor of Lyons. Since the French occupation the Malagasy have conformed pretty readily to the new order of things, although many of the most intelligent Hôva deeply regret that their country did not retain its independence. Justice is administered, on the whole, with fairness and impartially; but the taxation seems too heavy for the means of the people, indeed it is affirmed by trustworthy natives that the well-to-do classes are being greatly drained of their property. To an outsider it also appears that the staff of officials is very largely in excess of any real needs of administration; several monopolies, which interfere with the habits of the people, tend to produce discontent; and the taking of their land and houses for public works, roads, &c., while but a mere fraction of their real value is allowed as compensation, does not help to increase their acquiescence in foreign control. But the most serious cause for dislike to government action was the interference by the governor-general, in 1907, with their religious customs, by the suppression of hundreds of their congregational schools, and the closing of numbers of their churches.

In July 1910 M. Augagneur was replaced as governor-general by M. Picquière, a prominent official of the Colonial Department, who had previously served with acceptance as deputy governor-general of French Indo-China, and who had a reputation for tact and impartiality.

Christian Missions and Education.—As already noticed, the Malagasy were brought into connexion with the London Missionary Society, their first school system and their first literature, in 1820 and subsequent years; and for fifteen years all educational work was carried on by them, some 10,000 to 12,000 children having been instructed in their schools. On the reopening of the country to Europeans in 1862, the L.M.S. mission was resumed and was carried on with vigour for several years, stations being formed in several parts of Iméria, in the Betsileo and Antsianaka provinces, and at the ports of Antananà-ràiso, Majunga, and Fianarantsoa. In 1890 the number of their churches was 1230; adherents, 248,000; and scholars, 68,000; so that for long the greater part of the educational work was in their hands, carried on not only in primary schools, but also in high schools and colleges. In 1896 the Church of England began work in the island through the Society for the Propagation of the Gospel and the Church Missionary Society. After some time, however, the latter society withdrew, leaving the field to the L.M.S. and the English Church. The Malagasy have formed a theological college in its neighbourhood, but the chief work of the Anglican mission is on the east coast. In 1866 the Norwegian Lutheran Society began work in Madagascar, and was joined in 1888 by the American Missionary Society. The L.M.S. and the Church of England each have a large number of converts and (until lately) schools. In 1867 a mission was begun by the Society of Friends, who gave great attention to education and literary work, and afterwards took up their field of labour the western and south-western parts of Iméria, where they set up a large mission. Immediately after the island became a French possession, Protestant Churches began in (1896) to take part in the evangelizing of their new colony, and about half the area of the new population occupied by the London Missionary Society was transferred to the Paris Society. The bulk of the Malagasy Christians are Protestants, probably two-thirds or four-fifths of those professing Christianity. A Roman Catholic (Jesuit) mission was begun in 1862, and a large force of priests with a bishop and lay brethren and sisters engaged in education, have been working in the island since then, except during the two Franco-Malagasy wars. Since the French conquest, the north of the island has been occupied by a mission of priests of the Saint Esprit, and the southern portion by the Lazarist mission, each with a bishop at its head. The following table gives the statistics of the various Protestant missions at the close of 1906:

1. It is true that 200 years earlier than this, persistent efforts were made for nineteen years (1600-1619) by Portuguese Roman Catholic missionaries to propagate their faith among the south-east coast tribes, with little success, but through the zeal and self-sacrifice of these men, their efforts were abortive, and the mission was at length abandoned, leaving no fruit of their labours in a single church or convert. Half a dozen small books of devotion are all that remain to show their presence in Madagascar.

2. The work of the "Frères chrétiens" was, however, almost broken up by the anti-clerical policy of the French government.
Since 1897 high schools, and medical and technical schools, and a few primary schools, have been formed by the French government; and all other schools have been placed under regulations issued by an educational department, the scholars being required to learn the French language. As a result of this educational reform, the clerical work was carried on by the various missions. At that date the anti-clerical movement in France began to affect Madagascar. In all the missions the churches had, in the vast majority of cases, been set up, and the priests and brothers of the missions were forbidden to use churches for educational purposes after two months from that date; and the effect of the decree, with other provisions, was to close hundreds of schools, probably three-fourths of the whole number.

For many years (1862-1896), all medical aid to the sick, the formation of hospitals and dispensaries, the training of native doctors, midwives, and nurses, and the production of medical literature was entirely due to the Protestant missionaries, viz. the London Missionary Society, the Free Church of Scotland, the Society of Friends, and the Catholic Missionary Society of Madagascar. They all became a necessity in the course of the work in the country, and from 1862 to 1896 they were the only missionaries in the island. The medical schools of the Roman Catholic missions were carried on until 1897, but they were then closed and the government took over the work.

The medical schools of the Protestant missions were continued until 1897, but they were then closed and the government took over the work. The medical schools of the Roman Catholic missions were carried on until 1897, but they were then closed and the government took over the work.

MADDEN, SIR FREDERIC (1801-1873). English palaeographer, the son of an officer of Irish extraction, was born at Portsmouth on the 16th of February 1801. From his earliest years he displayed a strong bent to linguistic and antiquarian studies. In 1826 he was engaged by the British Museum to assist in the preparation of the classified catalogue of printed books then contemplated, and in 1828 he became assistant keeper of manuscripts. In 1833 he was knighted, and in 1837 succeeded Josiah Forshall as keeper of manuscripts. He was not entirely successful in this office, partly owing to want of harmony with his colleagues; he retired in 1866. He edited for the Roxburghe Club Havelok the Done (1828), discovered by himself among the Laudian MSS. in the Bodleian, William and the Wewolf (1832) and the old English versions of the Gesta Romanorum (1838). In 1839 he edited the ancient metrical romances of Syr Gawayne for the Bannatyne Club, and in 1847 Layamon’s Brut, with a prose translation, for the Society of Antiquaries. In 1850 the magnificent edition, in parallel columns, of what are known as the “Wycliflde” versions of the Bible, from the original MSS., upon which he and his coadjutor, Forshall, had been engaged for twenty years, was published by the university of Oxford. In 1886-1890 he edited the Historio Minor of Matthew Paris for the Rolls Series. In 1833 he wrote the text of Henry Shaw’s Illuminated Ornaments of the Middle Ages; and in 1850 edited the English translation of Silvestre’s Paléographie universelle. He died on the 8th of March 1873, bequeathing his journals and other private papers to the Bodleian Library, where they were to remain unopened until 1920.

Madden was perhaps the first palaeographer of his day. He was an acute as well as a laborious antiquary, but his ignorance of German prevented his ranking high as a philologist, although he paid close attention to the early days of the English language.

MADDER, or DYERS’ Madder, the root of Rubia tinctorum and perhaps also of R. peregrina, both European, R. cordifolia, a native of the hilly districts of India and of north-east Asia and Java, supplying the Indian madder or manjist. Rubia is a genus of about thirty-five species of the tribe Galiceae of the order Rubiaceae, and much resembles the familiar Galiums, e.g. lady’s bedstraw (G. verum) and the cleavers (G. aparine) of English hedges, having similarly whorled leaves, but the parts of the flowers are in fives and not fours, while the fruit is somewhat fleshy. The only British species is R. peregrina, which is found in Wales, the south and west of England, and in east and south Ireland. The use of madder appears to have been known from the earliest times, as cloth dyed with it has been found on the Egyptian mummies. It was the ερυθραφόρον used for dyeing the cloaks of the suction in the days of Herod (Herod. iv. 89). It is the λευκόροδωρον of Dioscorides, who speaks of its cultivation in Caria (iii. 160), and of Hippocrates (De morb. mul. i.). The Rubia of Pliny (xix. 17). R. tinctorum, a native of western Europe, &c., has been extensively cultivated in south Europe, France, where it is called garance, and Holland, and to a small extent in the United States. Large quantities have been imported into England from Smyrna, Trieste, Lethorn, &c. The cultivation, however, decreased after alizarin, the red colouring principle of madder, was made artificially. Madder was employed medicinally by the ancients and in the middle ages. Gerard, in 1597, speaks of it as having been cultivated in many gardens in his day, and describes its supposed many virtues (Herball, p. 560); but any pharmacological or therapeutic action which madder may possess is unrecognizable. Its most remarkable physiological effect is that of colouring red the bones of animals fed upon it, as also the claws and beaks of birds. This appears to be due to the chemical affinity of phosphate of lime for the colouring matter (Pereira, Mat. med., vol. ii. pt. 2. p. 52). This property has been of much use in enabling physiologists to ascertain the manner in which bones develop, and the functions of the various types of cells found in growing bone. R. chilensis has been used for dying red from time immemorial. The clay-root, which furnishes a red dye in Coromandel and other parts of India, is the root-bark of Oldenlandia umbellata, a low-growing plant of the same family as madder.

MADEC, RENÉ-MARIE (1736-1784)—called Medoc in Anglo-Indian writings—French adventurer in India, was born at Quimper in Brittany on the 7th of February 1736, of poor parents. He went out to India and served under Dupleix and Lally, but being taken prisoner by the British he enlisted in the Bengal army. Deserting with some of his companions shortly before the battle of Buxar (1764), he became military instructor to various native princes, organizing successively the forces of Shuja-ud-Dowlah, nawab of Oudh, and of the Jats and Rohillas. He took service under the emperor Shah Alam in 1772, and when that prince was defeated at Delah by the Mahrattas, Madec rejoined his own countrymen in Pondicherry, where he took an active part in the defence of the town (1778). After the capitulation of Pondicherry he returned to France with a considerable fortune, and died there in 1784. At one time he formed a scheme for a French alliance with the Mogul emperor against the British, but the project came to nothing.

See Émile Barbé, Le Nubab René Madec (1894).

MADEIRA, or THE MADEIRAS, a group of islands in the North Atlantic Ocean, which belong to Portugal, and consist of two inhabited islands named Madeira and Porto Santo and two groups of uninhabited rocks named the Desertas and Selvagens. Pop. (1900), 150,574; area, 314 sq. m. Funchal, the capital of the archipelago, is on the south coast of Madeira Island, in 32° 37′ 45″ N. and 16° 54′ W. It is about 360 m. from the coast of Africa, 535 from Lisbon, 1215 from Plymouth, 240 from Tenerife, and 480 from Santa Maria, the nearest of the Azores. Madeira (pop. 1900, 148,263), the largest island of the group, has a length of 30 m., an extreme breadth of 12 m., and a coastal area of 106 m. Its longer axis lies east and west, in which direction it is traversed by a mountain chain, the backbone of the island, having a mean altitude of 4000 ft., up to which many deep ravines penetrate from both coasts and render travel by land very difficult. Pico Ruivo, the highest summit, stands in the centre of the island, and has a height of 6036 ft., while some of the adjacent summits are very little lower. The depth and narrowness of the ravines, the loftiness of the rugged peaks, often covered with snow, that tower above them, the bold precipices of the coast, and the proximity of the sea, afford many scenes of picturesqueness beauty or striking grandeur. The greater part of the interior is uninhabited, though cultivated, for the towns, villages and scattered huts are usually built either at the mouths of ravines or upon the lower slopes that extend from the mountains to the coast. The ridges between the ravines usually terminate in lofty headlands, one of which, called Cabo Girão, has the height of 192 ft., and much the seashore is bounded by precipices of dark cliff.

The north coast, having been more exposed to the erosion of the sea, is more precipitous than the south, and presents everywhere a wilder aspect. On the south there is left very little of the indigenous forest which once clothed the whole island and gave it the name it bears (from the Portuguese madeira. Lat. materia, wood), but on the north some of the valleys still contain native trees of fine growth. A long, narrow and comparatively low rocky promontory forms the eastern extremity of the island; and here is a tract of calcareous sand, known as the Fossil Bed, containing land shells and numerous bodies resembling the roots of trees, probably produced by infiltration.

Porto Santo is about 25 m. N.E. of Madeira. Pop. (1900), 2311. It has a length of 63 m. and a width of 3 m. The capital is Porto Santo, called locally the vila or town. The island is very unproductive, water being scarce and wood wholly absent. Around the little town there is a considerable tract of pretty level ground covered by calcareous sand containing fossil land-shells. At each end of the island are hills, of which Pico do Facho, the highest, reaches the altitude of 1663 ft. Barley, but little else,
is grown here, the limited requirements of the inmates being supplied from Funchal.

The Desertas lie about 11 m. S.E. of Madeira, and consist of three islands, Ilheu Chão, Bugio and Desertas Grande, together with Sail Rock off the north end of Ilheu Chão. They present lofty precipices to the sea on all sides. Rabbits and goats abound on them. The archil weed grows on the rocks, and is gathered for exportation. The largest islet (Deserta Grande) is 6½ m. long, and attains the height of 1610 ft. These rocks are conspicuous objects in the sea-views from Funchal.

The Selvagens or Salvages are a group of three islands, 156 m. from Madeira, and between Madeira and the Canary Islands. The largest island is the Great Piton, 3 m. long, and 1 m. broad. The inclusion of the Selvagens in the Madeira Archipelago is due to political rather than to geographical reasons.

Geology.—All the islands of the group are of volcanic origin. They are the summits of very lofty mountains which have their bases in an abyssal ocean. The greater part of what is now visible in Madeira is of subaerial formation, consisting of basaltic and trachytic lavas, beds of tuff and other ejectamenta, the result of a long and complicated series of eruptions from innumerable vents. Besides the ash blown up by the eruptive matter from craters and clefts, a certain amount of upheaval in mass has taken place, for at a spot about 1200 ft. above the sea in the northern valley of São Vicente, and again at about the same height in Porto Santo, there have been found fragments of limonitic conglomerates containing marine shells and echinoderms of the Miocene Tertiary epoch. We have here proof that during or since that epoch portions of at least these islands have been bodily uplifted more than 1000 ft. The fossils are sufficiently well preserved to admit of their genera, and in many instances even their species, being made out.

There were pauses of considerable duration whilst the island of Madeira was being increased in height. The leaf bed and the accompanying carbonaceous matter, frequently termed the wood, although it displays no trace of structure, which lie under 1200 ft. of lavas in the valley of São Jorge, afford proof that there had been sufficient time for the growth of a vegetation of high order, many of the leaf impressions belonging to species of trees and shrubs which still exist on the island. Moreover, great alterations and dislocations had taken place in the rocks of various localities before other lavas and tuffs had been thrown upon them.

There are no data for determining when volcanic action began in this locality, but looking at the enormous depth of the surrounding sea it is clear that a vast period of time must have elapsed to allow of a great mountain reaching the surface and then rising several thousand feet. Again, considering the comparatively feeble agents for effecting the work of denudation (neither rain nor thick accumulations of alpine snow being found here), and then the enormous erosion which has actually taken place, the inference is inevitable that a very great lapse of time was required to excavate the deep and wide ravines that everywhere intersect the island. Nor is anything known as to the period of the cessation of volcanic action. At the present day there are no live craters or smoking crevices, as at the Canaries and Cape Verdes, nor any hot springs, as at the Azores.

In one of the northern ravines of Madeira by Porto da Cruz some masses of a coarsely crystalline Essesite are exposed to view; this rock is evidently the deep-seated representative of the Trachy-doleritic and Nepheline basalt lavas. Fragments of a sodalite-syenite have also been found at Soca in the same neighbourhood.

In the eastern part of the island several small crater rings are to be seen; their rims are formed of spheroidal basalt, while within the craters themselves masses of bauxite are found accompanied by blocks of fumarolic rock.

In the sections afforded by the ravines, which strike north and south from the central ridge of Madeira to the sea, the nucleus of the island is seen to consist of a confused mass of more or less basaltic rock, upon which rests a tuff, consist of tuffs, scoriae and lava, in the shape of basalt, trap and trachyte, the whole traversed by dykes. These beds are thinnest near the central axis; as they approach the coast they become thicker and less intersected by dykes.

Various parts are elevated tracts of comparatively level ground. These are supposed to have been formed by the meeting of numerous streams of lava flowing from cones and points of eruption in close proximity, various ejectamenta assisting at the same time to fill up inequalities. Deep down in some of the lateral ravines there may be seen ancient cones of eruption which have been overwhelmed by streams of melted matter issuing from the central region, and afterwards exposed to view by the same causes that excavated the ravines. These ravines may be regarded as having been formed at first by subterranean movements, both gradual and violent, which dislocated the rocks and cut clefts through which streams flowed to the sea. In course of time the waters, periodically swollen by melted snows and the copious rains of winter, would wear and deeper into the heart of the mountains, and would undermine the lateral cliffs, until the valleys became as large as we now find them. Even the Curral, which from its rounded shape and its position in the centre of the island has been casually described as a crater, is thought to be nothing more than a valley scooped out in the way described. The rarity of crateriform cavities in Madeira is very remarkable. There exists, however, to the east of Funchal, on a small but very high, the Lagoa, a small but perfect crater, 500 ft. in diameter, and with a depth of 150 ft.; and there is another, which is a double one, in the district known as Fanal, in the north-west of Madeira, nearly 5000 ft. above the sea. The basin, of which much of the outer part of the island is composed, is of a dark colour, and bears a topography smooth and well dissected by the same and augite. It is sometimes full of vesicular cavities, formed by the expansion of imprisoned gases. A rudely columnar structure is very often seen in the basalt, but there is nothing so perfect as the columnar structure of the Great Piton. The thickness of the lavas is, however, much less than that of the basaltic class. The tufa is soft and friable, and generally of a yellow colour; but where it has been overflowed by a hot stream of lava it has assumed a red colour. Black ash and fragments of pumice are sometimes found in the tufaceous strata.

There are no metallic ores, nor has any sulphur been found; but a little iron pyrites and specular iron are occasionally met with. The island has an excellent building-stone, various qualities of which are quarried near Camara de Lobos, five or six miles west of Funchal.

In Porto Santo the trachytic rocks bear a much greater proportion of augite than those of the Great Piton, in which carbonated and calcareous rock, indicating a submarine origin, upon which superimposed lavas have been poured. The older series contains corals and shells (also of the Miocene Tertiary epoch), with water-worn pebbles, containing both plant and animal remains, the lower appearing to have been a coral reef near an ancient beach. The calcareous rock is taken in large quantities to Funchal, to be burnt into lime for building purposes.

Climate.—Observations taken at Funchal Observatory (80 ft. above sea-level) in the penultimate ten years of the 19th century showed that the mean annual temperature is about 65° F. The mean minimum for the coldest part of the year (October to May inclusive) does not fall below 55°, and the average daily variation of temperature is about 10°. The island, however, is constantly subjected to the prevailing northerly winds which blow with great force. The prevalent winds are from the north or from a few points east or west of north, but these winds are much mitigated on the south coast by the cold ocean current of the Great Pitons. The west wind usually brings rain. That from the north is a dry wind which is less in force. At the eastern end of the island the wind occasionally blows from the east-south-east, the direction of the Sahara, and causes the hill region to be hotter than below; but even on the coast the thermometer under its influence sometimes indicates 93°. The least rain falls in July, and is 2.000 ft. The thermometer has never been known to fall as low as 46° at Funchal, frost and snow are there wholly unknown; but snow falls on the mountains once or twice during the winter, very seldom, however, below the altitude of 2000 ft. Thunderstorms are rare, and scarcely ever violent.
Madeira has long had a high reputation as a sanatory resort for persons suffering from diseases of the chest. Notwithstanding the ever-increasing competition of other winter resorts, a considerable number of invalids, especially English and German, winter at Funchal.

**Fauna.**—No species of land mammal is indigenous to the Madeiras. Some of the early voyagers indeed speak of wild goats and swine, but these animals must have escaped from confinement. The rabbit, black rat, brown rat and mouse have been introduced, but the first two kinds are rare. A small marsupial (Monachus albiventris), a blind mole (Isotricha passerina), and a few insects, especially the house fly and a species of butterfly, are in the Madeira fauna. The Praslin or Madeira bat (Myotis murina) is the only mammal of the genus to be found on the island. The Madeira rabbit (Oryctolagus cuniculus) has been introduced, but there are no other rabbits. About 250 species of marine fishes taken at Madeira have been scientifically determined, the largest family being Scorbutidae, with 35 species, of which nine are eggs. The species Atseus lunulatus, from the Laubride with 13, the Gadidae with 12, the eels with 12, the Percidae with 11, and the Carangidae with 10. Many such kinds, as the mackerel, horse mackerel, groper, mullet, bream, etc., are caught in abundance, but the Spanish mackerel (Scomber spp.) is the commonest of all. Several species of tunny are taken plentifully in spring and summer, one of them sometimes attaining the weight of 300 lb. The only freshwater fish is the common eel, which is found in one or two of the streams.

According to T. V. Wollaston (Testacea atlantica, 1879), there have been found 158 species of mollusca on the land, 6 inhabiting fresh water, and 7 littoral species, making a total of 171. A large majority of these species are shells, and they are all brought to light at the Madeiras. The proportion of endemic kinds is very large, and it is remarkable that 200 of them are either wingless or their wings are so poorly developed that they cannot fly, while of the endemic genera have been collected, the majority of these species have been collected, among them are some very interesting forms.

The only order of insects which has been thoroughly examined is that of the Coleoptera. By the persevering researches of T. V. Wollaston and others, no less than 150 new species have been brought to light at the Madeiras. Some of the species are variable in form or colour, and some have an extraordinary number of varieties. Of the land mollusca 91 species are assigned to the genus Helix, 31 to the genus Pupa, and 13 to the genus Achatina (or Loxoa). About 43 species are found both living and fossil in superficial deposits of calcareous sand in Madeira or Porto Santo. These deposits are assigned by Lyell to the Newer Pliocene period. Some 12 or 13 species have not been hitherto discovered alive. Moreover, various groups of animals have been collected, among them are some very interesting forms.

The bristle-footed worms of the coast have been studied by Pro-fessor P. Langerhans, who has met with about 200 species, of which a large number were new to science. There are no modern coral reefs, but several species of stony and flexible corals have been collected. There are also a few species of echinoderms, but the most interesting are the soft corals, which are much in evidence. There are many species of sponges, but the most interesting is a white stony coral allied to the red coral of the Mediterranean which would be valuable as an article of trade if it could be obtained in sufficient quantity. Of some are rare and handsome red Paragorgia, Ysyea, and usua species. The forms above mentioned are all monotypic species of the Family Pachyceratidae.

**Flora.**—The vegetation is strongly impressed with a south-European character. Many of the plants in the lower region undoubtedly were introduced and naturalized after the Portuguese colonization. A large number of the remaining are found at the Canaries, and a few are relics of the flora of Madeira before the introduction of the canaries. In the Madeiras there are about a hundred plants which are peculiarly Madeiran, either as distinct species or as strongly marked varieties. The flowering plants found truly wild belong to about 363 genera and 717 species—-the monocotyledons number about 70 genera and 153 species, the dicotyledons 293 genera and 586 species. The three largest orders are the Compositae, Leguminosae and Gramineae.

Forty-one species of ferns grow in Madeira, three of which are endemic species and six others belong to the peculiar flora of the North Atlantic islands. About 100 species of moss have been collected, and 47 species of Hepaticae. The vegetation of Madeira is rich in the lowlands, and that of the West Indies and tropical America has been inferred from the presence of six ferns found nowhere in Europe or North Africa, but existing on the islands of the east coast of South America, and on the West Indies. A further relationship to that continent is to be traced by the presence in Madeira of the beautiful ericaceous tree Clethra arborea, belonging to a genus which is otherwise wholly American, and of a Persea, a tree laurel, also an American plant. Amongst the trees most worthy of note are four of the laurel order belonging to separate genera, Anardia, Pittosporum, Sideroxylon, Notelasia, Rhamni and Myrica—a strange mixture of genera from different parts of the world. A further relationship to that continent is indicated by a woody plant cover large rocks on the mountains. In some parts there is a belt of the Spanish chestnut about the height of 1300 ft. There is no indigenous pine tree as at the Canaries; but large trees on the hills have been planted with Pinus pinaster, from which the fuel of the inhabitants is mainly derived. A European juniper (J. oxycedrus), growing to the height of 40 or 50 ft., was formerly abundant, but has been almost exterminated, as its scented wood is prized by the cabinet-maker. Several of the native trees and shrubs now grow only in situations which are necessarily inaccessible, and some of the indigenous plants are of the greatest rarity. But some plants of foreign origin have spread in a most thorough manner. The olive and fig (Ficus carica) grow luxuriantly on the south coast, and the myrtle leaves (Opuntia Tuna), which in many spots on the coast is sufficient to give a character to the landscape. As to Algae, the coast is too rocky and the sea too quiet for a luxuriant marine vegetation. The inhabitants.—The inhabitants are of Portuguese descent, with probably some intermixture of Moorish and negro blood among the lower classes. The dress of the peasants, without being picturesque, is peculiar. Both men and women in the outlying country districts wear the carrapucu, a small cap made of blue cloth in shape something like a funnel, with the pipe standing upwards. The men have trousers of linen, drawn tight, and terminating at the knees; a coarse shirt enveloping the upper part of their person, covered by a short jacket, completes their attire, with the exception of a pair of rough yellow boots. The women’s outer garments consist of a gaudily coloured gown, made from island material, with a small cape of coarse scarlet or blue woollen cloth. The population tends to increase rapidly. In 1800 it amounted to 150,574, including 890 foreign, of whom the majority were British. The number of females exceeds that of males by about 6000, partly because many of the able-bodied males emigrate to Brazil or the United States. The density of population is about 10 to the sq. m. It is very great for a district containing no large town and chiefly dependent on agriculture and viticulture.

**Agriculture.**—A large portion of the land was formerly entailed in the families of the landlords (morgados), but entails have been abolished by the legislature, and the land is now absolutely free. The deficiency of water is a great obstacle to the proper cultivation of the land, and the rocky nature or steep inclination of the upper parts of the islands is an effectual bar to all tillage. An incredible amount of labour has been expended upon the soil, partly in the erection of walls intended to prevent its being washed away by the rains, and to build up the plots of ground in the form of terraces. Watercourses have been constructed for purposes of irrigation, without which at regular intervals the island would not produce a hundredth part of its present yield. These watercourses originate high up in the ravines, are built of masonry, and as they descend, are cut into terraces and kept in good order for miles and miles until they reach the cultivated land. Some of them are brought by tunnels from the north side of the island through the central crest of hill. Each occupier takes his turn at the running stream for so many hours in the day or night at a time notified to him beforehand. In this climate flowing water has a saleable value as well as land, which is useless without irrigation.

The agricultural implements employed are of the roughest kind, and the system of cultivation is extremely primitive. Very few of the occupiers own the land they cultivate; they almost invariably own the walls, cottages and trees standing on the hillside alone belonging to the landlord. The tenant can sell his share of the property without the consent of the landlord, and if he does not so...
dispose of that which share passes to his heirs. In this way the tenant practically enjoys fixity of tenure, for the landlord is seldom in a position to pay the price at which the tenant's share is valued. Money rents are rare, the métayer system regulating almost universally the relations between landlord and tenant. In Madeira, and indeed to the owner a portion of the produce, usually one half or one third. The holdings are as a rule rarely larger than one man can cultivate with a little occasional assistance. There are few meadows and pastures. Persons are added to the feeding of cattle, horses are never employed for draught, all labour of that kind being done by oxen.

The two staple productions of the soil are wine and sugar. The vine was introduced to Cyprus or Crete soon after the discovery of the island by the Portuguese (1420), but it was not actively cultivated until the early part of the 16th century. The vines, after having been totally destroyed by the oidium disease, which made its first appearance on the island in 1501, were renewed in a few years wine was again made. The phylloxera also made its way to the island, and every vineyard in Madeira was more or less affected by it. The vineyards terminated by trees and in the shape of terraces. Madeira is made from a mixture of black and white grapes, which are also made separately into wines called Tinta and Verdelho, after the names of the grapes. Other high-class wines, known as Bual, Sercial and Malvasia, are made from varieties of grapes bearing the same names. (See also Wine.)

The sugar cane is said to have been brought from Sicily about 1452, and in course of time its produce became the sole staple of the island. The sugar was shipped in the market and to the markets of tropical countries came into the European market, and sugar had long ceased to be made when the destruction of the vines compelled the peasants to turn their attention to other things. Its cultivation is accompanied by rare and sugar machinery imported, and a considerable quantity of spirit is made by the distillation of the juice or of the molasses left after extracting the sugar, and this is consumed on the island. The cane does not flourish luxuriantly as within the tropics; but in localities below 1000 ft., where there is a good supply of water, it pays the cultivator well.

The grain produced on the island (principally wheat, barley and Indian corn) is not sufficient for the consumption of the people. The common potato, sweet potato and gourds of various kinds are extensively grown, as well as the Colocasis esculenta, the kalo of the Pacific islands, the root of which yields an insipid food. Most of the vegetables grown in Madeira are of the same order, as Beemor apples, pears and peaches, all of poor quality, oranges, lemons, guavas, mangoes, loquats, custard-apples, figs, bananas and pineapples are produced, the last two forming articles of export. The date still is occasionally grown, but its fruit is scarce and small. The hills large quantities of the Spanish chestnut afford an item in the food of the common people. A little tobacco is grown, and is made into cigars of inferior quality.

The foreign trade of Madeira was valued at £625,000 in 1900. The principal exports are wine, sugar, embroidery, vegetables, fruits and wicker goods. Coal is imported for the ships calling at Funchal, which is the headquarters of Madeiran commerce and industry. Sugar beet, cotton, wool, woolen goods, tobacco, hats and leather, are manufactured for home consumption, and there are important fisheries.

Chief Towns and Communications.—Funchal (pop. 20,850) is described in a separate article. The other chief towns are Camara de Lobos (7150), Machico (6128), Santa Cruz (5876) Ponta do Sol (5662), São Vicente (4896), Calheta (3472), Sant' Anna (3011) and Porto Santo (2311). Each of these is the capital of a commune (concelho), to which it gives its name. Madeira is connected by regular lines of steamships with Great Britain, Germany, Portugal, Cape Colony, Brazil and the United States. There is no railway in the archipelago, and partly owing to the irregularities of the surface of the roads, of which there are some 580 m., are bad, except in the neighbourhood of Funchal. Wheel chairs on short legs are the means of locomotion for the backs of mules or upon rude wooden sledges drawn by bullocks. When horses are not employed, locomotion is effected either by means of hammocks or by bullock cars. The ham-mock (ridé) is a piece of stout canvas gathered up and secured at each end to a pole carried by a couple of bearers. In place of cars, curtained cars on sledges, made to hold four persons, and drawn by a pair of bullocks, are employed. They are convenient, but the rate of progress is very slow.

Administration.—The archipelago is officially styled the district of Funchal; it returns members to the Portuguese Cortes, and is regarded as an integral part of the kingdom. The district is subdivided into the eight communes already enumerated, and is administered in accordance with the same laws that regulate local government on the mainland (see PORTUGAL). Funchal is a Roman Catholic bishopric in the archipelagic province of Lisbon. Education is compulsory in name only, for less than 2% of the population could read when the census of 1900 was taken. An infantry regiment and a battery of garrison artillery are permanently stationed in Madeira.

History.—It has been conjectured, but on insufficient evidence, that the Phoenicians discovered Madeira at a very early period. Pliny mentions certain Purple or Mauretanian Islands, the position of which with reference to the Fortunate Islands or Canaries might seem to indicate the Madeiras. There is a romantic story, to the effect that two lovers, Robert Machim, a Machim, or Macham, and Anna d’Arfet, fleeing from England to France (c. 1370) were driven out of their course by a violent storm and cast on the coast of Madeira at the place subsequently named Machico, in memory of one of them. Both perished here, but some of the crew escaped to the Barbary coast, and were made slaves. Among them was the pilot Pedro Morales de Seville, who is said to have been ransomed and to have communicated his knowledge of Madeira to João Gonçalvez Zarco (or Zargo). How far this story is true cannot now be ascertained. It is, however, certain that Zarco first sighted Porto Santo in 1418, having been driven thither by a storm while he was exploring the coast of West Africa. Madeira itself was discovered in 1420. It is probable that the whole archipelago had been explored at an earlier date by Genoese adventurers, and had been forgotten; for an Italian map dated 1351 (the Laurentian portolanos) shows the Madeiras quite clearly, and there is some reason to believe that they were known to the Genoese before 1350. When Zarco visited Madeira in 1420 the islands were uninhabited, but Prince Henry the Navigator at once began their colonization, aided by the knights of the Order of Christ. Sanctioned by the pope and by two charters which the king of Portugal granted in 1430 and 1433, the work proceeded apace; much land was forested and brought into cultivation, and the Madeiran sugar trade soon became important. For the sixty years 1580—1640 Madeira, with Portugal itself, was united with Spain. Slavery was abolished in Madeira in 1775, by order of Pombal. In 1801 British troops, commanded by General Beresford, occupied the island for a few months, and it was again under the British flag from 1807 to 1814. It shared in the civil disturbances brought about by the accession of Dom Miguel (see PORTUGAL: History), but after 1833 its history is a record of peaceful commercial development.

See A. A. Brown, The Canaries and the Azores (1903), a comprehensive study of the three archipelagos. The Land of the Wine, by A. J. D. Bidwell (Philadelphia, 1901) is generally valuable, but its history cannot be trusted. See also P. Langhorst, Handbuch für Madeira (1884) and Vahl, Madeira's Vegetation (Copenhagen, 1904).

MADELENIAN, a term derived from La Madeleine, a cave in the Vézère, about midway between Moustier and Les Eyzeys, France, and given by the French anthropologist Gabriel de Mortillet to the third stage of his system of cave-chronology, synchronous with the fourth or most recent division of the Quaternary Age. The Madeleiniyen epoch was a long one, represented by numerous stations, whose contents show progress in the arts and general culture. It was characterized by a cold and dry climate, the existence of man in association with the reindeer, and the extinction of the mammoth. The use of bone and ivory for various implements, already begun in the preceding Solutrian epoch, was much increased, and the period is essentially a Bone age. The bone instruments are very varied: spear-points, harpoon-heads, borers, hooks and needles. Most remarkable is the evidence La Madeleine affords of prehistoric art. Numbers of bones, reindeer antlers and animals' teeth were found, with rude pictures, carved on them, of seals, fishes, reindeer, mammoths and other creatures. The best of these are a mammoth engraved on a fragment of its own ivory; a dagger of reindeer antler, with handle in form of a reindeer; a cave-bear cut on a flat piece of schist; a seal on a bear's tooth; a fish well drawn on a reindeer antler; and a complete picture, also on reindeer antler, showing horses, an aurochs, trees, and a snake biting a man's leg. The man is naked, and this and the snake suggest a warm
climates in spite of the presence of the reindeer. The fauna of the Madeleian epoch seems, indeed, to have included tiger and other tropical species side by side with reindeer, blue foxes, Arctic hares and other polar creatures. Madeleian man appears to have been of low stature, dolichocephalic, with low retreating forehead and prominent brow ridges. Besides La Madeleine the chief stations of the epoch are Les Eyzies, Laugerie Basse, and Gorge d'Enfer in Dordogne; Grotte du Placard in Charente and others in south-west France.

**MADELEY**—a market town in the municipal borough of Wrenlock, and the Wellington (Mid) parliamentary division of Shropshire, England, 150 m. N.W. from London, with stations on the London & North Western (Madeley Market) and Great Western railways (Madeley Court). Pop. of civil parish (1901), 8442. There are large ironworks, ironstone and coal are mined, and potter's clay is raised. The church of St Michael (1796) replaced a Norman building. The living was held from 1760 to 1783 by John William Fletcher or de la Flèchère, a close friend of the Wesleys. The parish includes a portion of Coalbrookdale (q.v.), and the towns of Ironbridge and Coalport. Ironbridge, a town picturesquely situated on the steep left bank of the Severn, adjoins Madeley on the south-west. It takes its name from the iron bridge of one span crossing the river, erected in 1779. This bridge is a remarkable work considering its date; it was probably the first constructed, at any rate, on so large a scale, and attracted great attention. It is the work of Abraham Darby, the third of the name, one of the famous family of iron-workers in Coalbrookdale. Here are brick and tile works and lime-kilns. There is a station (Ironbridge and Broseley) on the Great Western railway, across the river. Coalport lies also on the Severn, S. of Madeley, and 2 m. S.E. of Ironbridge, with a station on the Great Western railway. It has large china works, founded at the close of the 18th century, which subsequently incorporated those of Caughley, across the Severn, and of Nantgarw in Glamorganshire.

**MĀDHAVA ĀCHĀRYA** (B. c. 1386), Hindu statesman and philosopher, lived at the court of Vijayanagar (the modern Humpi in the district of Bellary), the vigorous Southern Hindu kingdom that so long withstood Mahommedan influence and aggression. He was a brother of Jayacharya, whom he associated with him in the administration and was a famous commentator on the *Rigveda*. Śāyaṇa's commentaries were influenced by and dedicated to Mādhava, who is best known as the author of the *Saṃvarasāra Samgraha* (*Compendium of Speculations*). With remarkable mental detachment he places himself in the position of an adherent of sixteen distinct systems. Mādhava also wrote a commentary on the *Mimamsā Sūtras*. He died as abbot of the monastery of Sringeri.

**MĀDI** (A-MADI), a negro race of the Nile valley, occupying both banks of the Bahr-al-Jebel immediately north of Albert Nyanza. Tradition makes them immigrants from the north-west. They are remarkable for the consideration shown to their women, who choose their own husbands, are never ill-treated or humiliated, and are not seized in war. Their society is patriarchal. They are good agriculturists, and build sepulchral monuments of an elaborate type, two huge narrow stones sloping towards each other with two smaller slabs covering the opening between them. They have been much harried by the Azande and Abaramo. They were visited by W. Junker in 1882-1883, and described by him in *Petermann's Mittheilungen* for May 1883.

**MADISON, JAMES** (1751-1836), fourth president of the United States, was born at Port Conway, in King George county, Virginia, on the 16th of March 1751. His first ancestor in America may possibly have been Captain Isaac Maddyson, a colonist of 1632 mentioned by John Smith as an excellent Indian fighter. His father, also named James Madison, was the owner of large estates in Orange county, Virginia. In 1769 the son entered the college of New Jersey (now Princeton University), where, in the same year, he founded the well-known literary club, "The American Whig Society." He graduated in 1771, but remained for another year at Princeton studying, apparently for the ministry, under the direction of John Witherspoon (1722-1794). In 1772 he returned to Virginia, where he pursued his reading and studies, especially theology and Hebrew, and acted as a tutor to the younger children of the family. In 1775 he became chairman of the committee of public safety for Orange county, and wrote its response to Patrick Henry's call for the arming of a colonial militia, and in the spring of 1776 he was chosen a delegate to the new Virginia constitution, where he was on the committee which drafted the constitution for the state, and proposed an amendment (not adopted) which declared that "all men are equally entitled to the full and free exercise of religion, and was more radical than the similar one offered by George Mason. In 1777, the Confederation was on the eve of collapse, and the Madison scheme for a central authority was an ingenious attempt to avoid the failure of the states to respond to requisitions of Congress for supplies for the federal treasury, Madison was among the first to advocate the granting of additional powers to Congress, and urged that congress should forbid the states to issue more paper money. In 1781 he was a member of the Virginia legislature, which considered the Virginia delegates wholly subject to its instructions, he advocated that the states should grant to Congress for twenty-five years authority to levy an import duty, and suggested a scheme to provide for the interest on the debt not raised by the import duty—appropriating it among the states on the basis of population, counting three-fifths of any Maryland negroes. Accompanying this plan was an address to the states drawn up by Madison, and one of the ablest of his state papers. In the same year, with Oliver Ellsworth of Connecticut, Nathaniel Gorham of Massachusetts, Gunning Bedford of Delaware, and John Rutledge of South Carolina, he was a member of the committee which reported on the Virginia proposal as to the terms of cession to the Confederation of the "back lands," or unoccupied Western territory, held by several of the states; the report was a skillful compromise made by Madison, which secured the approval of the rather exigent Virginia legislature.

In November 1783 Madison's term in Congress expired, and he returned to Virginia and took up the study of the law. In the following year he was elected to the House of Delegates. As a member of the convention of 1788 he signed the Virginia ratification of the Constitution. He opposed the proposed assessment, drawn up at the suggestion of George Nicholas (c. 1755-1799), was widely circulated and procured its defeat. On the 26th of December 1783 Jefferson's Bill for establishing religious freedom in Virginia, which had been introduced by Madison, was passed. In the Virginia House of Delegates, as in the Continental Congress, he opposed the further issue of paper money; and he tried to induce the legislature to repeal the law confiscating British debts, but he did not lose sight of the interests of the Confederacy. The boundary between Virginia and Maryland, according to the Baltimore grant, was the south shore of the Potomac, a line to which Virginia had agreed on condition of free
navigating the river and the Chesapeake Bay. Virginia now feared that too much had been given up, and desired joint regulation of the navigation and commerce of the river by Maryland and Virginia. On Madison's proposal commissioners from the two states met at Alexandria (q.v.) and at Mount Vernon in March 1785. The Maryland legislature approved the Mount Vernon agreement and proposed to invite Pennsylvania and Delaware to join in the arrangement. Madison, seeing an opportunity for more general concord in regard to commerce and trade (and possibly for the increase of the power of Congress), proposed that all the states should be invited to send commissioners to consider commercial questions, and a resolution to that effect was adopted (on Jan. 21, 1786) by the Virginia legislature. This led to the Annapolis convention of 1786, and that in turn led to the Philadelphia convention of 1787. In April 1787, Madison had written a paper, The Vices of the Political System of the United States, and from his study of confederacies, ancient and modern, later summed up in numbers 17, 18, and 19 of The Federalist, he had concluded that no confederacy could long endure if it acted upon states only and not directly upon individuals. As the convention for a new government drew near, he drew up an outline of a new system of government, the basis of the "Virginia plan" presented in the convention by Edmund Jennings Randolph. Madison's scheme, as expressed in a letter to Washington dated the 16th of April 1787, was that individual sovereignty of states was irreconcilable with aggregate sovereignty, but that the "consolidation of the whole into one simple republic would be as inexpedient as it is unattainable." He considered as a practical middle ground changing the basis of representation in Congress from states to population; giving the national government "positive and complete authority in all cases which require uniformity"; giving it a negative on all state laws, a power which might best be vested in the Senate, a comparatively permanent body; electing the lower house, and the more numerous, for a short term; providing for a national executive, for extending the national supremacy over the judiciary and the militia, for a council to revise all laws, and for an express statement of the right of coercion; and, finally, obtaining the ratification of a new constitutional instrument by the people, and not merely by the legislatures. The "Virginia plan" was the basis of the convention's deliberations which resulted in the constitution favourably voted on by the convention on the 17th of September 1787. Among the features of the plan which were not embodied in the constitution were the following: proportionate representation in the Senate and the election of its members by the lower house "out of a proper number of persons nominated by the individual legislatures"; the vesting in the national Congress of power to negative state acts; and the establishment of a council of revision (the executive and a convenient number of national judges) with veto power over all laws passed by the national Congress. Madison, always an opponent of slavery, disapproved of the compromise (in Art. 1. §9 and Art. V.) postponing to 1808 (or later) the prohibition of the importation of slaves. He took a leading part in the debates of the convention, of which he kept full and careful notes, afterwards published by order of Congress (3 vols., Washington, 1843). Many minute and illuminating references are due to him, he spoke before the convention more frequently than any delegate except James Wilson and Gouverneur Morris. In spite of the opposition to the constitution of the Virginia leaders George Mason and E. J. Randolph, Madison induced the state's delegation to stand by the constitution in the convention. His influence largely shaped the form of the final draft of the constitution, but the labour was not finished with this draft; that the constitution was accepted by the people was due in an eminent degree to the efforts of Madison, who, to place the new constitution before the public in its true light, and to meet the objections brought against it, joined Alexander Hamilton (q.v.) and John Jay in writing The Federalist, a series of eighty-five papers, out of which twenty certainly, and nine others probably, were written by him. In the Virginia convention for ratifying the constitution (June 1788), when eight states had ratified and it seemed that Virginia's vote would be needed to make the necessary nine (New Hampshire's favourable vote was cast only shortly before that of Virginia), and it appeared that New York would vote against the constitution if Virginia did not ratify it, Madison was called upon to defend that instrument again, and he appeared at his best against its opponents, Patrick Henry, George Mason, James Monroe, Benjamin Harrison, William Grayson and John Tyler. He answered their objections in detail, calmly and with an intellectual power and earnestness that carried the convention. The result was a victory against an originally adverse public opinion and against the eloquence of the opponents of the constitution, for Madison and for his lieutenants, Edmund Pendleton, John Marshall, George Nicholas, Harry Innes and Henry Lee. At the same time Madison's labours in behalf of the constitution alienated from him valuable political support in Virginia. He was defeated by Richard Henry Lee and William Grayson in his candidacy for the United States Senate, but in his own district he was chosen a representative to Congress, defeating James' Monroe, who seems to have had the powerful support of Patrick Henry. Madison took his seat in the House of Representatives in April 1789, and resumed a less active part in legislation necessary to the organization of the new government. He drafted a Tariff Bill giving certain notable advantages to nations with which the United States had commercial treaties, hoping to force Great Britain into a similar treaty; but his policy of discrimination against England was rejected by Congress. It was his belief that such a system of retaliation would remove the possibility of war arising from commercial quarrels. He introduced resolutions calling for the establishment of three executive departments, foreign affairs, treasury and war, the head of each removable by the president. Most important of all, he proposed nine amendments to the constitution, embodying suggestions made by a number of the ratifying states, especially those made by Virginia at the instance of George Mason; and the essential principles of Madison's proposed amendments were included in a Bill of Rights, adopted by the states in the form of ten amendments. The absence of a Bill of Rights from the constitution as first adopted had been the point on which the opposition had occasioned the Convention; and the adoption of this now greatly weakened the same opposition. Although a staunch friend of the constitution, Madison believed, however, that the instrument should be interpreted conservatively and not be made the means of introducing radical innovations. The tide of strict construction was setting in strongly in his state, and he was borne along with the flood. It is very probable that Jefferson's influence over Madison, which was greater than Hamilton's, contributed to this result. Madison now opposed Hamilton's measures for the funding of the debt, the assumption of state debts, and the establishment of a National Bank, and on other questions he sided more and more with the opposition, gradually assuming its leadership in the House of Representatives and labouring to confine the powers of the national government within the narrowest possible limits; his most important argument against Hamilton's Bank was that the constitution did not provide for it explicitly, and could not properly be construed into permitting its creation. Madison, Jefferson and Randolph were consulted by Washington, and they advised him not to sign the bill providing for the Bank, but Hamilton's counter-argument was successful. On the same constitutional grounds Madison opposed to the carrying out of the recommendations in Hamilton's famous report on manufactures (Dec. 5, 1791), which favoured a protective tariff. In the presidential campaign of 1792 Madison seems to have lent his influence to the determined efforts of the Jeffersonians to defeat John Adams by electing George Clinton vice-president. In 1793-1796 he strongly criticized the administration for maintaining a neutral position between Great Britain and France, writing for the public press five papers (signed " Helvidius"), attacking the "monarchical prerogative of the executive" as exercised in the proclamation of neutrality in 1793 and denying the president's right to recognize foreign states. He found in Washington's attitude—as in Hamilton's failure to pay an instalment of the moneys
due France—an "Anglied complexion," in direct opposition to the popular sympathy with France and French Republicanism. In 1794 he tried again his commercial weapons, introducing in the House of Representatives resolutions based on Jefferson's report on commerce, advising retaliation against Great Britain and discrimination in commercial and navigation laws in favour of France; and he declared that the friends of Jay's treaty were "a British party systematically aiming at an exclusive connexion with the British government," and in 1796 strenuously but unsuccessfully opposed the appropriation of money to carry this treaty into effect. Still thinking that foreign nations could be coerced through their commercial interests, he scouted as visionary the idea that Great Britain would go to war on a refusal to carry Jay's treaty into effect, thinking it inconceivable that Great Britain "would wantonly make war" upon a country which was the best market she had in the world for her manufactured articles, and which her export trade was so much larger than her import.

In 1797 Madison retired from Congress, but not to a life of inactivity. In 1798 he joined Jefferson in opposing the Alien and Sedition Laws, and Madison himself wrote the resolutions of the Virginia legislature declaring that it viewed "the powers of the Federal government as resulting from the compact to which the states are parties, as limited by the plain sense and intention of the instrument constituting that compact; as no further valid than they are authorized by the grants enumerated in that compact; and that, in case of a deliberate, palpable and dangerous exercise of other powers, not granted by the said compact, the states, who are parties thereto, have the right and are in duty bound to interpose for arresting the progress of the evil, and for maintaining within their respective limits, the authorities, rights and liberties appertaining to them." The Virginia resolutions and the Kentucky resolutions (the latter having been drafted by Jefferson) were met by dissenting resolutions from the New England states, from New York, and from Delaware. In answer to these, Madison, who had become a member of the Virginia legislature in the autumn of 1799, wrote for the committee to which they were referred a report elaborating and susto in every point the phraseology of the Virginia resolutions.1

Upon the accession of the Republican party to power in 1801, Madison became secretary of state in Jefferson's cabinet, a position for which he was well fitted both because he possessed to a remarkable degree the gifts of careful thinking and discreet and able speaking, and of large constructive ability; and because he was well versed in constitutional and international law and particularly in the questions to be discussed in connection with the Peace of 1814. During the eight years that he held the portfolio of state, he had continually to defend the neutral rights of the United States against the encroachments of European belligerents; in 1806 he published An Examination of the British Doctrine which subjects to Capture a Neutral Trade not open in Time of Peace, a careful argument—with a minute examination of authorities on international law—against the rule of war of 1756 extended by Great Britain in 1793 and 1803.

1 Thirty years later Madison's arguments for the Virginia resolutions and the resolutions themselves were freely used by Calhoun and Calhoun to found the doctrine of nullification. Madison insisted that the Resolutions of 1798 did not involve the principles of nullification. Nearly all his arguments, especially where he attempts to interpret Jefferson's writings on the point, notably the Kentucky resolutions, are rather strained and specious, but it does seem that the Virginia resolutions were based on a different idea from Calhoun's doctrine of nullification. Madison's theory was that the legislature of Virginia, being one of the belligerents, had a right to regulate the expenses in the supreme cabinet, but was legally capable of considering the question of the constitutionality of laws passed by the Federal government, and that the state of Virginia might invoke other states to join her, but could not singly, as Calhoun argued, declare any law of the Federal legislation null and void. (It is to be noted the words "null and void" were in Madison's first draft of the Virginia resolutions, but that they were omitted by the Virginia legislature.) It is notable, besides, that Madison had warned Calhoun that the national congress would assume too great power, that he had approved of Supreme Court checks on the national legislature, and of veto power by a council of revision.

During Jefferson's presidency and whilst Madison was secretary of state, by the purchase of Louisiana, Madison's campaign began in 1780 for the free navigation of the Mississippi was brought to a successful close. The candidate in 1808 of the Republican party, although bitterly opposed in the party by John Randolph and George Clinton, Madison was elected president, defeating C. C. Pinckney, the Federalist candidate, by 122 votes to 107. Madison had no false hopes of placating the Federalist opposition, but as the preceding administration was one with which he was in harmony, his position was different from that of Jefferson in 1801, and he had less occasion for removing Federalists from office.

Jefferson's peace policy—or, more correctly, Madison's peace policy—of commercial restrictions to coerce Great Britain and France he continued to follow until 1812, when he was forced to change these futile commercial weapons for a policy of war, which was very popular with the extreme French wing of his party. There is a charge, which has never been proved or disproved, that Madison's real desire was for peace, but that in order to secure the renomination he yielded to that wing of his party which was resolved on war with Great Britain. The only certain fact is that Madison, whatever were his personal feelings in this matter, acted according to the wishes of a majority of the Republicans; but whether in doing so he was influenced by the desire of another nomination is largely a matter of conjecture. Madison was renominated on the 18th of May 1812, issued his war message on the 1st of June, and in the November elections he was re-elected, defeating De Witt Clinton by 128 votes to 80. His administration during the war was pitifully weak. His cabinet in great part had been dictated to him in 1809 by a senatorial clique, and it was hopelessly discordant; for two years he was to all intents and purposes his own secretary of state, Robert Smith being a mere figure-head of whom he gladly got rid in 1811, giving Monroe the vacant place. Madison himself had attempted alternately to prevent war by his "commercial weapons" and to prepare the country for war, but he had met with no success, because of the tricky diplomacy of Great Britain and of France, and because of the general distrust of him coupled with the particular opposition to the war of the prosperous New England Federalists, who suggested with the utmost seriousness that his resignation should be demanded. In brief, Madison was too much the mere scholar to prove a strong leader in such a crisis. The supreme disgrace of the administration was the capture and partial destruction in August 1814 of the city of Washington—this was due, however, to incompetence of the military and not to any lack of prudence on the cabinet's part. In general, Congress was never more搅and never allowed to be—perfectly composed of soldiers or the army officers. With the declaration of peace the president again gained a momentary popularity much like that he had won in 1809 by his apparent willingness at that time to fight France.

Retiring from the presidency in 1817, Madison returned to his home, Montpelier (in Orange county, Virginia), which he left in no official capacity save in 1829, when he was a delegate to the state constitutional convention and served on several of its committees. Montpelier, like Jefferson's Monticello and Monroe's Oak-Hill, was an expensive bit of "gentleman farming," which with his generous Virginia hospitality nearly ruined its owner financially. Madison's home was peculiarly a centre for literary travellers in his last years; when he was eighty-three he was visited by Harriet Martineau, who reported her conversations with him in her Retrospect of Western Travel (1831). He took a great interest in education—his library was left to the university of Virginia, where it was burned in 1865—in emancipation, and in agricultural questions, to the very last. He died at Montpelier on the 28th of June 1836. Madison married, in 1794, Dorothy Payne Todd (1772-1849), widow of John Todd, a Philadelphia lawyer. She had great social charm, and upon Madison's entering Jefferson's cabinet became "first lady" in Washington society. Her plump beauty was often remarked—notably by Washington Irving—in contrast to her husband's delicate and feeble figure and wizened face—for even in his prime Madison was, as Henry Adams says, "a small man, quiet, somewhat precise in manner, pleasant, fond of conversation, with a certain
mixture of ease and dignity in his address." Her son, spoiled by his mother and his step-father, became a wild young fellow, and added his debts to the heavy burden of Montpelier upon Madison.

Madison's portrait was painted by Gilbert Stuart and by Charles Willson Peale; Giuseppe Ceracchi made a marble bust of him in 1792 and John H. J. Brower another in 1827, now in possession of the Virginia Historical Society at Richmond. Though commonly dignified by his contemporaries, he was somewhat a clown, with a love of humour and he was fond of telling a good story. Henry Clay, contrasting him with Jefferson, said that Jefferson had more genius, Madison more judgment and common sense; that Jefferson was a visionary and a theoretician; Madison cool, dispassionate, practical, and safe.1 The broadest and most accurate scholar among the "founders and fathers," he was particularly an expert in constitutional history and theory. In the great causes for which Madison fought—the right of free speech and press, religious freedom and separation of church and state, the free navigation of the Mississippi, and the adoption of the constitution—he met with success. His greatest and truest fame is as "the father of the constitution." The commercial weapons with which he wished to prevent armed conflict proved less useful in his day than they have since been in international disputes.

Authorities.—Madison's personality is perplexingly vague; the biographies of him are all less than half the period of the history of the period in which he was before the public, Henry Adams' History of the United States from 1789 to 1817 (1869), gives the clearest sketch and best criticism of him. The lives of Madison are: J. Q. Adams' (Boston, 1850); W. C. Rivers' (Boston, 1859-1860), covering the period previous to 1797; S. II. Gay's (Boston, 1884) in the "American Statesmen Series"; and Guillard Hunt's (New York, 1902). Madison's Writings (vols., New York), was also the work of Hunt and of Doubleday. The Journal of the Debates in the Convention which framed the Constitution of the United States, as Recorded by James Madison (2 vols., New York, 1808). See also Mrs Madison's Memoirs and Letters (Boston, 1856) and Maud Wiltier Goodwin, Dolly Madison (New York, 1897).

MADISON, a city and the county-seat of Jefferson county, Indiana, U.S.A., on the N. bank of the Ohio river, about 90 m. below Cincinnati, and 44 m. above Louisville, Kentucky. Pop. (1870), 10,700; (1890), 8,936; (1900), 7,835 (554 foreign-born and 570 negroes); (1910), 6,934. Madison is served by the Pittsburg, Cincinnati & St Louis railroad and by river steamboats. The city is picturesqueely situated on bluffs above the river and has two public parks. In Madison are a King's Daughters' Hospital, a children's home, and the Drusilla home for old ladies, and immediately north of the city are the buildings of the Indiana South-eastern Insane Hospital. Madison is a trading centre of the surrounding farming region, whose principal products are barley tobacco, grain and fruits (peaches, apples, pears, plums and small fruits). The municipality owns and operates the waterworks. Madison was settled about the beginning of the 19th century; was incorporated as a town in 1831, and first chartered as a city in 1856.

MADISON, a borough of Morris county, New Jersey, U.S.A., 27 m. (by rail) W. of New York City and 4 m. S.E. of Morris-town. Pop. (1800), 2,459; (1890), 3,754, of whom 975 were foreign-born and 300 were negroes; (1900), 4,115; (1910), 4,656. It is served by the Morris & Essex division of the Delaware, Lackawanna & Western railroad. The borough is attractively situated along the banks of Upper New Jersey, is primarily a residential suburb of New York and Newark, and contains many fine residences. There are a public library and a beautiful public park, both given to the borough by Daniel Wilis James (1832-1907), a prominent metal manufacturer; the library is closely allied with the public schools. Madison is the seat of the well-known Drew theological seminary (Methodist Episcopal; founded in 1822 and opened 1824); named in 1878, the Drew theological seminary (1788-1819), having acquired great wealth from steamboat and railway enterprises, especially from trading in railway stocks, presented the large and beautiful grounds and most of the buildings of the seminary's course covers three years; no fee is charged. In connexion with the seminary the Drew settlement in New New York City—officially the department of applied Christianity—has for its object the "practical study of present-day problems in city evangelism, church organization, and work among the poor." In 1907-1908 the seminary had 9 instructors, 175 students, and a library of more than 160,000 volumes, especially rich in works dealing with the history of Methodism and in Greek New Testament manuscripts. About 2 m. N.W. of Madison is Convent Station, the seat of a convent of the Sisters of Charity, who here conduct the college of St Elizabeth, for girls, founded in 1839; also conducted by the Sisters of Charity is St Joseph's preparatory school for boys, founded in 1862. The cultivation of roses and chrysanthemums is practically the only industry of Madison. Madison owns and operates its waterworks and electric-lighting plant. Before 1844 when it took its present name (in honour of President Madison), Madison was called Bottle Hill; it is one of the older places of the state, and its first church (Presbyterian) was built about 1748. The borough was incorporated in 1886.

MADISON, the capital of Wisconsin, U.S.A., and the county-seat of Dane county, situated between Lakes Mendota and Monona in the southern central part of the state, about 82 m. W. of Milwaukee and about 131 m. N.W. of Chicago. Pop. (1890), 13,426; (1900), 19,164, of whom 3362 were foreign-born and 69 were negroes; (1910 census) 25,531. Madison is served by the Chicago & North-Western, the Chicago, Milwaukee & St Paul, and the Illinois Central railways (which the northern terminus of the last), and by interurban electric lines, connecting with Janesville, Beloit and Chicago. It has a picturesque situation in what is known as "the Four-Lakes region"; this region takes its name from a chain of lakes, Kegonsa, Waubesa, Monona and Mendota, which, lying in the order named and connected with one another by the Yahara or Catfish River form the head-waters of Rock river flowing southward through Illinois into the Mississippi. The city occupies a hilly isthmus about a mile wide between Lakes Mendota and Monona, bodies of water of great clearness and beauty, with bottoms of white sand and granite.

The state capitol is in a wooded park at the summit of a hill 85 ft. high in the centre of the city. From this park the streets and avenues radiate in all directions. The capitol, built in 1861-1867 (with an addition in 1883) on the site of the original capitol building (1837-1839), was partially destroyed by fire in 1904, and in 1909-1910 was replaced by a larger edifice. The principal business portion of the city is built about the capitol park and the university. Among the public buildings on or near the capitol grounds are the Supreme Court building, built by the United States courts, the city hall, the Dane county court-house, the public library, the Fuller opera-house, the county jail, and the high school. Running directly west from the capitol is State Street, at the western end of which lie the grounds of the university of Wisconsin (q.v.), occupying a hilly wooded tract of 300 acres, and extending for a mile along the shore of Lake Mendota. University Hill, on which the main building of the university stands, is 125 ft. above the lake; at its foot stands the magnificent library building of the State Historical Society. In it, in addition to the interesting and valuable historical museum and art gallery, are the society's library of more than 350,000 books and pamphlets, the university library of 150,000 volumes, and the library of the Wisconsin academy of arts and sciences, 5000 volumes. Other libraries in the city include the state law library (45,000 volumes) in the capitol, the Madison public library (22,500 volumes), and the Woodman astronomical library (7500 volumes). The Madison public library houses also the state library building, maintained by the Wisconsin library commission. Connected with the university is the Washburn observatory. On the margin of the city lies the extensive experimental farm of the state college of agriculture. In addition to the state university, Madison is the seat of several Roman Catholic and Lutheran parochial schools, two business schools, and the Wisconsin academy, a non-sectarian preparatory school of high grade. On the banks of Lake Monona are the beautiful grounds of the Monona Lake assembly, a summer assembly

1 Clay's opinion is given in a report written by Mrs Samuel H. Smith of a conversation in 1829 between Clay and her husband, a prominent politician.
on the Chautauqua model. Near the city is one of the five fish-hatcheries maintained by the state; it is largely devoted to the propagation of trout and other small fish. North of the city, occupying a tract of 500 acres, on Lake Mendota, are the buildings and grounds of the state hospital for the insane, opened in 1860.

The city's streets are broad and heavily shaded with a profusion of elm, oak and maple trees. There are many fine stone residences dating from the middle of the 19th century. There are several parks of great beauty, and along the shores of Lake Mendota there is a broad boulevard drive of 12 m. The municipality owns its waterworks, the water being obtained from eleven artesian wells, and being chemically similar to that of Waukesha Springs. The city and surrounding region are a summer resort, the lakes affording opportunities for fishing and for yachting and boating.

Madison is an important johnny center for central and south-western Wisconsin; it has an extensive trade in farm, garden and dairy products, poultry and tobacco; and there are various manufactures. In 1905 the value of the total factory product was $3,201,143, an increase of 22.4% over that in 1900.

At the time of the settlement by the whites the aboriginal inhabitants of the Four-Lakes region were the Winnebago. Prehistoric earthworks are to be seen in the neighbourhood, several animal-shaped mounds upon the shores of Lake Mendota, Monona and Waubesa being among the best examples. A regular trading post is known to have been established on Lake Mendota as early as 1820. The title to the Indian lands was acquired by the United States by treaty in 1825. Colonel Ebenezer Brigham established himself at Blue Mounds, in the western part of Dane county, in 1827. In 1832 the "Four-Lakes" country was in the theatre of hostilities during the Black Hawk war; Colonel Henry Dodge held a conference with Winnebago chiefs on Lake Mendota, and there were several skirmishes in the neighbourhood between his troops and the followers of Black Hawk, one of which took place on the site of Madison. After Black Hawk's defeat on the Bad Axe he fled to the Wisconsin river Dalles, near the present Kilbourn, where he was betrayed by the Winnebago. In 1836 Stevens T. Mason, governor of Michigan, and James Duane Doty, then U.S. district judge, who had visited the region as early as 1829, recorded a tract of land, including most of the present site of Madison. Here they surveyed a "paper" city which they named in honour of James Madison. On the 3rd of December 1836 the territorial legislature in session at Belmont, after a protracted and acrimonious debate, determined, largely through Doty's influence, to make Madison the permanent capital. The construction of houses began in the early spring of 1837. The first constitutional convention met here in 1846, the second in 1847. Madison was chartered as a city in 1856. In 1862 a large number of Confederate prisoners were confined in Camp Randall, at Madison, and many of them died in hospital.

See D. S. Durrie, History of Madison, Wisconsin (Madison, 1874); Lyman C. Draper, Madison the Capital of Wisconsin (Madison, 1857); J. D. Butler, "The Four Lakes Country" in Wisconsin Historical Collections, vol. 10 (1888), and R. G. Thwaites, "Madison," in Historic Towns of the Western States (New York, 1900), and his Story of Madison in The University of Wisconsin (Madison, 1900).

MADOU, JEAN BAPTISTE (1796-1877), Belgian painter and lithographer, was born at Brussels on the 3rd of February 1796. He studied at the Brussels Academy of Fine Arts and was a pupil of François. While draughtsman to the topographical military division at Courtrai, he received a commission for lithographic work from a Brussels publisher. It was about 1830 that he began his artistic career. Between 1825 and 1832 he contributed to Les Vues pittoresques de la Belgique, a Life of Napoleon, and to works on the costumes of the Netherlands, and later made a great reputation by his work in La Physionomie de la société en Europe depuis 1800 jusqu'à nos jours (1836) and Les Scènes de la vie des peintres.

It was not until about 1840 that he began to paint in oils, and the success of his early efforts in this medium resulted in a long series of pictures representing scenes of village and city life, including "The Fielder," "The Jewels Merchant," "The Police Court," "The Drunkard," "The Ill-regulated Household," and "The Village Politicians." Among his numerous works mention may also be made of "The Feast at the Château" (1851), "The Unwelcome Guests" (1852, Brussels Gallery), generally regarded as his masterpiece, "The Rat Hunt" (acquired by Leopold II., king of the Belgians), "The Arquebusier" (1860), and "The Stirrup Cup." At the age of sixty-eight he decorated a hall in his house with a series of large paintings representing scenes from La Fontaine's fables, and ten years later made for King Leopold a series of decorative paintings for the château of Clergnon. Madou died at Brussels on the 31st of March 1877.

For a list of his paintings see the annual report of the Academy of Belgium for 1879.

MADOZ, PASCUAL (1806-1870). Spanish statistician, was born at Pampluna on the 7th of May 1806. In early life he was settled in Barcelona, as a writer and journalist. He joined the Progresista party formed during the first Carlist war, 1833-40. He saw some service against the Carlists; was elected deputy to the Cortes of 1836; took part for Espartero, and then against him; was imprisoned in 1843; went into exile and returned; was governor of Barcelona in 1854, and minister of finance in 1855; had a large share in secularizing the Church lands; and after the revolution of 1868 was governor of Madrid. He had, however, no great influence as a leader and soon went abroad, dying at Genoa in 1870. Madoz was distinguished from most of the politicians of his generation by the fact that in middle life he compiled what is still a book of value—a geographical, statistical and historical dictionary of Spain and its possessions overseas, Diccionario geográfico, estadístico y histórico de España, y sus posesiones de Ultramar (Madrid, 1848-1850).

MADRAS, a presidency of British India—officially styled Fort St George—occupying, with its dependencies, the entire south of the Indian peninsula. The north boundary is extremely irregular. On the extreme N.E. is the Bengal province of Orissa; then the wild highlands of the Central Provinces; next the dominions of the nizam of Hyderabad; and lastly, on the N.W., the Bombay districts of Dharwar and North Kanara. Geographically Mysore and Coorg lie within the bounds of Madras, and politically it includes the Laccadive Islands, off the Malabar coast, in the Indian Ocean. Its total area, including native states, is 131,665 sq. m., and its population in 1901 was 42,997,523, showing an increase of 7.7% in the decade. The seat of government is at Madras city (q.v.).

Physical Aspect.—The Madras presidency may be roughly divided into three tracts: (1) the long and broad east coast, (2) the shorter and narrower west coast, and (3) the high interior table-land. These divisions are determined by the great mountain ranges of the Eastern and Western Ghats (q.v.). Between these two ranges lies the Deccan plateau, an upland region bounded on the north by the Western Ghats, and across the peninsula in a south-east direction into the Bay of Bengal. In the upper parts of their course they drain rather than water the country through which they flow, and are comparatively valueless either for navigation or irrigation; but, as they approach the plains, as in the smaller rivers on the east coast and the Western Ghats, they form the chief sources of the Deccan, and are navigable and irrigating. The rivers of the same character are the Pennar and South Pennar or Ponniar, Palar, Vaigai, Vellar and Tambraparni. The principal lake is that of Pulicat on the east coast, which is 37 m. long from north to south, and forms an important means of communication between Madras city and the northern districts. On the west coast are a remarkable series of backwaters or lagoons, fringing the seaboard of Kanara, Malabar and Travancore. The largest is the backwater of Cochin, which extends 120 m. from north to south.

tribe is the Todas (q.v.). The Mahommedans are subdivided into Labbai, Moplah, Arab, Sheikh, Sayad, Pathan, and Mughal. The Labbaïs are the descendants of Hindu converts, and are traders by hereditary occupation, although many now employ themselves as sailors and fishermen. The Moplahs are the descendants of Malayalam converts to Islam—the head of the tribe, the raja of Cannanore, being descended from a fisher family in Malabar. They are a hard-working, rough people, but quite uneducated and fanatical, and under the influence of religious excitement have often disturbed the public peace. Christians are more numerous in Madras than in any other part of India. In Travancore and Cochin states the native Christians constitute as much as one-fourth of the population. The Roman Catholics, whose number throughout southern India is estimated at upwards of 650,000, owe their establishment to St Francis Xavier and the famous Jesuit mission of Madura; they are partly under the authority of the archbishop of Goa, and partly under twelve Jesuit vicarates. Protestant missions date from the beginning of the 18th century. The Danes were the pioneers; but their work was taken up by the Society for Promoting Christian Knowledge, under whom laboured the great Lutherans of the 18th century—Schultz, Sarriortus, Fabricius and Schwartz. The Church Missionary Society entered the field in 1814; and subsequently an American mission joined in the work.

Languages.—Broadly speaking, the entire population of Madras belongs to the five linguistic offshoots of the great Dravidian stock, dominant throughout southern India. At an early period, before the dawn of history, these races appear to have accepted some form of the Brahmanical or Buddhist faiths. Many storms of conquest have since swept over the country, and colonies of Mogul and Makratha origin are to be found here and there. But the evidence of language proves that the ethnic character of the population has remained stable under all these influences, and that the Madras Hindu, Mahommedan, Jain and Christian are of the same stock. Of the five Dravidian languages in British territory Tulu is spoken by over 14,000,000 persons; Tamul by over 15,000,000 persons; Kanarese by over 1,500,000 persons; Malayalam by nearly 3,000,000 persons; and Tulu by about 500,000 persons. Orya is the native tongue in the extreme north of Ganjam, bordering on Orissa; and various sub-dialects of Dravidian origin are used by the hill tribes of the Eastern Ghats, of whom the Konhds may be taken as the type.

Agriculture.—Over the greater part of the area of Madras artificial irrigation is impossible, and cultivation is dependent upon the local rainfall, which rarely exceeds 40 in. a year, and is liable to fail entirely for years together. The coast is the only part of Madras that can be brought by the south-west monsoon may be trusted both for its amount and regularity. Other districts, such as Bellary, are also depopulated by this monsoon; but in their case the rainclouds have spent themselves in passing over the Western Ghats, and cultivation becomes a matter of hazard. Over the greater part of the presidency the rainy season is caused by the south-east monsoon, which breaks about the end of September. The deltas of the Godavari, Kistna and Cauvery rivers are the only spots on the coast where artificial irrigation is able to save from the risk of occasional scarcity. The principal food staples are rice, cholam, cambu, ragi and varagu (four kinds of millet). The chief spices are pepper, cardamom, gingselly (sesamum), and garden crops comprise tobacco, sugar-cane, chilies, betel leaf and plantains. Sugar is chiefly derived from the sap of palms. The fruit trees are coco-nut, areca-nut, palmaya palm, jack, tamarind and mango. Special crops include cotton, indigo, coffee, tea, cinchona. The best cotton is grown in Tinnevelly. The principal coffee tract stretches along the slopes of the Western Ghats from the north-central area of Erode, and the Nilgiri hills are within Madras. The first coffee plantation was opened in the Wynaad in 1840. Many of the early plantations proved unprofitable, and the enterprise made little progress till about 1855. Coffee is now much cultivated on the Nilgiri, covers about 100 sq. miles, though the area formerly cultivated is brought into the Nilgiri hills about 1840, but was not taken up as a commercial speculation till 1865, and is still unimportant. The cinchona plant was successfully introduced into the Nilgiri hills by the government in 1860, and there are a few plantations belonging to private owners.

The greater part of the soil in Madras is held by the cultivators.
MADRAS

direct from the government under the tenure known as ryotwari. Besides these lands in the hands of the government, there are also proprietary or zamindari estates in all parts of the country. These estates are either the remains of ancient principalities, which the holders of which have hereditary life tenure, or are creations of British rule and subject to the usual Hindu custom of partition. The total area of the zamindari estates is about 26 million acres, more than one-fourth of the whole presidency. The pecuniary revenue due to government in perpetuity amounts to about £330,000 a year.Indians, revenue-free or quit-rent grants of lands made for religious endowments or for services rendered to the state, occupy an aggregate area of nearly 6 million acres.

Manufactures.—Madrass possesses few staple manufactures. The chief industries of the presidency are cotton-ginning, coffee-currying, fish-currying, indigo-pressing, oil-pressing, printing, rice-currying, rope-making, sugar-refining, tanning, tile and brick-making, and tobacco-currying. The greater part of coffee is grown in the districts of Tanjore, Madura, and Salem, the main article of export. Masulipatam, where the first English factory on the Coromandel coast was established in 1629, enjoyed a special reputation for its chintzes, which were valued for the freshness and permanency of their dyes. There is still a small demand for these articles in Burma, the Straits, and the Persian Gulf; but Manchester goods have nearly beaten the Indian exporter out of the field. Native looms, however, still hold their own in the local market, in face of strenuous opposition. After working, working in metals appears to be the most widespread native industry. Among local specialties which have attracted European curiosity may be mentioned the jewelry of Trichinopoly, ornaments of ivory and horn worked in the same place, and sandalwood figures in Kanchipuram.

Commerce and Trade.—The continuous seaboard of the Madras presidency, without any natural harbours of the first rank, has tended to create a widely diffused trade. Madras city conducts a large coasting trade, and there are sea-borne communications with ports on the west coast, containing the western railway terminus near Calicut; then Godavari, with its cluster of ports along the fringe of the delta; Tinnevelly, with the harbour at Tuticorin, which has opened large dealings with Ceylon, and to the south, Masulipatam, the native port of Madura. As compared with the other provinces, the trade of Madras is broadly marked by the larger proportion assigned to coasting trade with other Indian ports and with Ceylon. The chief staples of the export are cotton and silk, coffee and raw cotton; those of the import, indigo, dyes, tea, and sugar.

Railways and Irrigation.—The presidency is well supplied with railways, which naturally have their centre in Madras city, the chief seaport. The broad-gauge line of the Madras & Southern Mahratta railway, which connects Madras with Bombay and Bangalore, and also crosses the peninsula to Calcutta on the western coast. The South Indian (narrow-gauge) serves the extreme south, with its terminus at Tuticorin, and branches to Tinnevelly, Nagapattinam, Erode, Pondicherry and Nellore. The narrow-gauge line of the Madras & Southern Mahratta railway traverses the Deccan districts; and the East Coast line (broad-gauge), through the Northern Circars, has brought Madras into direct communication with Calcutta. The Madras system of irrigation is marked by a network of canals in the plains of the great eastern rivers, the Godavari, Kistna, and Cauvery. Each of these is intercepted by an anicut or dam at the head of its delta, from which canals diverge on each side for navigation as well as irrigation. The principal rivers divide the watershed of the Periyar (a tributary of the Kistna) over the thirsty uplands of Kurnool province. The bold project of leading the Periyar river through a tunnel across the watershed of the Trancavore hills on to the plain of Madras has been more successful.

Administration.—The Madras presidency is administered by a governor and a council, consisting of two members of the civil service, which number may be increased to four. There is also a board of revenue of three members. The number of districts is 24, each under the charge of a collector, with sub-collectors and assistants. The districts are not grouped into divisions or commissions, as in other provinces. For legislative purposes the council of the governor is augmented by additional members, numbering 45 in all, of whom not more than 17 may be nominated officials, while 19 are elected by various representative constituencies. Members of the legislative council enjoy the right of interpellation, of proposing resolutions on matters of public interest, and of discussing the annual financial statement. The principle of local devolution is carried somewhat further in Madras than in other provinces. The landed interests are represented by the panchayats, whose chief duty is to attend to sanitation. Above them come taluk or subdivisional boards. At the head of all are district boards, a portion of whose members are elected by the taluk boards.

Education.—The chief educational institutions are the Madras University, the Presidency College, Madras Christian College, and Pachayyappas College at Madras; the government arts colleges at Combaconum and Rajahmundry; the law college, medical college and engineering college at Madras; the college of agriculture at Coimbatore; the teachers' college at Saidapet; the school of arts at Madras; and the military ophthalmic at Ootacamund, in memory of Sir Henry Lawrence. In 1907, the total number of pupils at all institutions was 1,007,118, of whom 164,706 were females, and 1,328,527 were learning English.

History.—Until the British conquest the whole of southern India had never acknowledged a single ruler. The difficult nature of the hill passes and the warlike character of the hill tribes forbade the growth of great empires, such as succeeded one another on the plains of Hindustan. The Tamil country in the extreme south is traditionally divided between the three kingdoms of Pandya, Chola and Chera. The west coast supplied the nucleus of a monarchy which afterwards extended itself to the highlands of Mysore, and took its name of the Carnatic. On the north-east the kings of Kalinga at one time ruled over the entire line of seaboard from the Kistna to the Ganges. Hindu legend has preserved marvellous stories of these early dynasties, but our only authentic evidence consists in their inscriptions on stone and brass, and their noble architecture (see INDIA). The Mahomedan invader first established himself in the south in the beginning of the 14th century. Ala-ud-din, the second monarch of the Khilji dynasty at Delhi, and his general Malik Kafur conquered the Deccan, and overthrew the kingdoms of Karnatak and Telingana, which were then the most powerful in southern India. But after the withdrawal of the Musulman armies the native monarchy of Vijayanagar arose out of the ruins. This dynasty gradually extended its dominions from sea to sea, and reached a pitch of prosperity before unknown. At last, in 1586, it was overthrown by a combination of the feared Coromandel principalities of the Deccan. At the close of the reign of Akbar, although that emperor nominally extended his sovereignty as far as Cape Comorin, in reality South India had again fallen under a number of rulers who owned no regular allegiance. The nizam of the Deccan, himself an independent sovereign, represented the distant court of Delhi. The most powerful of his feudatories was the nawab of the Carnatic, with his capital at Arcot. In Tanjore, a descendant of Sivaji ruled; and on the central table-land a Hindu chief-tain was gradually establishing his authority and founding the state of Mysore, destined soon to pass to a Mahomedan usurper.

Vasco da Gama cast anchor off Calicut on the 20th of May 1498, and for a century the Portuguese retained in their control the commerce of India. The Dutch began to establish themselves on the ruin of the Portuguese at the beginning of the 17th century, and were quickly followed by the English, who established themselves at Calicut and Cranganore in 1664. Tellicherry became the principal English emporium on the west coast of Madras. The Portuguese eventually retired to Goa, and the Dutch to the Spice Islands. The first English settlement on the east coast was in 1611, at Masulipatam, even then celebrated for its fabrics. Farther south a fort, the nucleus of Madras city, was erected in 1640. Pondicherry was purchased by the French in 1662. For many years the English and French traders lived peacefully side by side, and with no ambition for territorial aggrandisement. The war of the Austrian succession in Europe lit the first flame of hostility on the Coromandel coast. In 1746 Madras was forced to surrender to La Bourdonnais, and Fort St David remained the only English possession in southern India. By the peace of Aix-la-Chapelle Madras was restored to the English; but from that time the rivalry of the two nations was keen, and found its opportunities in the disputed successes which always fill a large place in Oriental politics. English influence was generally able to secure the favour of the rulers of the Carnatic and Tanjore, while the French succeeded in placing their own nominee on the throne at Hyderabad. At last Duplex rose to be the temporary arbiter of the fate of southern
India, but he was overthrown by Clive, whose defence of Arcot in 1751 forms the turning point in Indian history. In 1760 the crowning victory of Wandewash was won by Colonel (afterwards Sir Eyre) Coote, over Lally, and in the following year, despite help from Mysore, Pondicherry was captured.

Though the English had no longer any European rival, they had yet to deal with Mahomedan fanaticism and the warlike population of the highlands of Mysore. The dynasty founded by Hyder Ali, and terminating in his son Tippoo Sultan, proved itself in four several wars, which terminated only in 1799, the most formidable antagonist which the English had ever encountered (see HYDER Ali and INDA). Since the beginning of the 19th century Madras has known no regular war, but occasional disturbances have called for measures of repression. The pagars or local chieftains long clung to their independence after their country was ceded to the British. On the west coast, the feudal aristocracy of the Nairs, and the religious fanaticism of the Mahajans, have more than once rebelled and bloodshed. In the extreme north, the wild tribes occupying the hills of Ganjam and Vizagapatam have only lately learned the habit of subordination. In 1836 the zamindari of Gumsur in this remote tract was attached by government for the rebellious conduct of its chief. An inquiry then instituted revealed the widespread among the tribe of Kondhs of human sacrifice, under the name of meriah. The practice has since been suppressed by a special agency. In 1870 the country round Rampa on the northern frontier was the scene of riots sufficiently serious to lead to the necessity of calling out troops. The same necessity arose three years later, when the Hindus and Mahomedans of Salem came into collision over a question of religious ceremonial. A more serious disturbance was that known as the "Anti-Shanar riots" of 1890. The Maravans of Tinnevelly and parts of Madura, resenting the pretensions of the Shanars, a toddy-drawing caste, to a higher social and religious status, repeatedly attacked the Shanar villages. The town of Sivakasi was looted and burnt by five thousand Maravans. Quiet was restored by the military, and a punitive police force was stationed in the disturbed area.

The different territories comprising the Madras presidency were acquired by the British at various dates. In 1763 the tract encircling Madras city, then known as the Jagir now Chingleput district, was ceded by the nawab of Arcot. In 1765 the Northern Circars, out of which the French had recently been driven, were granted to the Company by the Mogul emperor, but at the price of an annual tribute of Rs.50,000 to the nizam of Hyderabad. Full rights of dominion were not acquired till 1813, when the tribute was commuted for a lump payment. In 1792 Tippoo was compelled to cede the Baramahal (now part of Salem district), Malabar and Dinigul subdivision of Madura. In 1799, on the reconstruction of Mysore state after Tippoo's death, the territory was granted to the Company by the Mogul emperor, but at the price of an annual tribute of Rs.50,000 to the nizam of Hyderabad. Full rights of dominion were not acquired till 1813, when the tribute was commuted for a lump payment. In 1800 Bellary and Cuddapah were made over by the nizam of Hyderabad to defray the expense of an increased subsidiary force. In the following year the dominions of the nawab of the Carnatic, extending along the east coast almost continuously from Nellore to Tinnevelly, were assigned into the hands of the British by a puppet who had been put upon the throne for the purpose. The last titular nawab of the Carnatic died in 1855; but his representative still bears the title of prince of Arcot, and is recognized as the first native nobleman in Madras. In 1830 the nawab of Kurnool was deposed for misgovernment and suspicion of treason, and his territories annexed.

See Madras Manual of Administration, 3 vols. (Madras, 1885 and 1893); S. Ayyangar, Forty Years' Progress in Madras (Madras, 1843); A. S. Roes, Madras (Society of Arts, 1901); Madras Provincial Gazetteer (2 vols., Calcutta, 1908).

**Madras**

The capital of Madras presidency, and the chief seaport on the eastern coast of India, is situated in 13° 4' N. and 80° 17' E. The city, with its suburbs, extends nine miles along the sea and nearly four miles inland, intersected by the little river Cooum. Area, 27 sq. m.; pop. (1901), 509,346, showing an increase of 12-6% in the decade. Madras is the third city in India.

Although at first sight the city presents a disappointing appearance, and possesses not a single handsome street, it has several buildings of architectural pretensions, and many spots of historical interest. It is spread over a very wide area, and many parts of it are almost rural in character. Seen from the roadstead, the fort, a row of merchants' offices, a few spires and public buildings are all that strike the eye. Roughly speaking, the city consists of the following divisions. (1) George Town (formerly Black Town, but renamed after the visit of the Prince of Wales in 1906), an ill-built, densely-populated block, about a mile square, is the business part of the town, containing the banks, custom house, high court, and all the mercantile offices. The last, for the most part handsome structures lie on either side of the thoroughfare. On the sea-face of George Town are the pier and the new harbour. Immediately south of George Town there is (a) an open space which contains Fort St George, the Marina, or fashionable drive and promenade by the seashore, Government House, and several handsome public buildings on the sea-face. (3) West and south of this lung of the city are crowded quarters known by native names—Chintadrapet, Turuvaleswaram, Pudupak, Royapet, Kistampet and Mylapur, which bend to the sea again at the old town of Saint Thome. (4) To the west of George Town are the quarters of Veperi and Pudupet, chiefly inhabited by Eura-sians, and the suburbs of Egmore, Nagambakam, and Perambur, adorned with handsome European mansions and their spacious compounds or parks, which make Madras a city of magnificent distances. (5) South-west and south lie the European quarters of Tannampet and aristocratic Adyar. Among the most notable buildings are the cathedral, Scottish church, Government House, Pachayappa's Hall, senate house, Chepauk palace (now the revenue board), and the Central railway station.

Madras possesses no special industries. There are several cotton mills, large cement works, iron foundries and cigar factories. Large sums of money have from time to time been spent upon the harbour works, but without any great success. The port remains practically an open roadstead, protected by two breakwaters, and the P. & O. steamers ceased to call in 1898. Passengers or cargo are landed or embarked in flat-bottomed masula boats. The sea bottom is unusually flat, reaching a depth of ten fathoms only at a mile from the shore. The harbour is not safe during a cyclone, and vessels have to put out to sea. Madras conducts about 56% of the foreign trade of the presidency, but a much smaller share of the coasting trade. As the capital of southern India, Madras is at the centre on which all the great military roads converge. It is also the terminal station of the two main lines of railways, the Madras & Southern Mahntra line and the Madras & Tanjore section of the South Indian railway. The Buckingham canal, which passes through an outlying part of the city, connects South Arcot district with Nellore and the Kistna and Godavari system of canal navigation. The municipal government of the city was framed by an act of the Madras legislature passed in 1884. The governing body consists of 32 commissioners, of whom 24 are elected by the ratepayers, together with a paid president. The Madras University was constituted in 1857, as an examining body, on the model of the university of London. The chief educational institutions in Madras city are the Presidency College; six missionary colleges and one native college; the medical college, the law college, the college of engineering, the teachers' college in the suburb of Saldapet, all maintained by government; and the government school of arts. The foundation of Madras dates from 1650, when Francis Day, chief of the East India Company's settlement at Armagon, obtained a grant of the present site of the city from a native ruler. A fort—called Fort St George, presumably from having been finished on St George's Day (April 23)—was at once
MADRAZO Y KUNT, DON FEDERICO DE (1815-1894), Spanish painter, was born in Rome on the 12th of February 1815. He was the son of the painter Madrazo y Agudo (1758-1850), and received his first instruction from his father. While still attending the classes at the Academy of San Fernando he painted his first picture, "The Resurrection of Christ" (1829), which was purchased by Queen Christina. Not long afterwards he painted "Achilles in his Tent," and subsequently presented to the Academy "The Continence of Scipio," which secured him admission as a member "for merit." While decorating the palace of Vista Alegre he took up portraiture. In 1852 he went to Paris, where he studied under Winterhalter, and painted portraits of Baron Taylor and of Ingres. In 1857 he was commissioned to produce a picture for the gallery at Versailles, and painted "Godfrey de Bouillon proclaimed King of Jerusalem." The artist then went to Rome, where he worked at various subjects, sacred and profane. Then he painted "Maria Christina in the Dress of a Nun by the bedside of Ferdinand III." (1843), "Queen Isabella," "The Duchess of Medina-Celi," and "The Countess de Vilchés" (1843-1847), besides a number of portraits of the Spanish aristocracy, some of which were sent to the exhibition of 1855. He received the Legion of Honour in 1846. He was made a corresponding member of the Paris Academy of Fine Arts on the 10th of December 1853, and in 1873, on the death of Schnorr, the painter, he was chosen foreign member. After his father's death he succeeded him as director of the Prado Gallery and president of the Academy of San Fernando. He originated in Spain the production of art reviews and journals, such as El Artista, El Renacimiento and El Semanario pintoresco. He died at Madrid on the 11th of June 1894. His brother, DON LOUIS DE MADRAZO, was also known as a painter, chiefly by his "Burial of Saint Cecilia" (1855). Don Federico's best-known pupil was his son, DON RAIMUNDO DE MADRAZO (b. 1841).

MADRID, a province of central Spain, formed in 1833 of districts previously included in the provinces of Burgos, Ávila, Segovia, Soria, and La Rioja, and containing the districts of Madrid, Guadalajara, Alcalá de Henares, and Alcalá de Henares. It is bounded on the W. and N. by Ávila and Segovia, E. by Guadalajara, S.E. by Cuenca and S. by Toledo. Pop. (1900), 1,075,034, of whom 539,835 inhabit the city of Madrid; area, 3084 sq. m. Madrid belongs to the basin of the Tagus, being separated from that of the Douro by the Sierra de Guadarrama on the N.W. and N., and by the Sierra de Gredos on the S.W. The Tagus is the southern boundary for some distance, its chief tributary being the Jarama, which rises in the Somosierra in the north and terminates at Aranjuez. The Jarama, in turn, is joined by the Henares and Tajuña on the left, and by the Lozoya and Manzanares on the right. The Guadarrama, another tributary of the Tagus, has its upper course within the province. Like the rest of Castile, Madrid is chiefly of Tertiary formation; the soil is mostly clayey, but there are tracts of sandy soil. Agriculture is somewhat backward; the rainfall is deficient, and the rivers are not utilized as they might be for irrigation. The south-eastern districts are the best watered, and produce in abundance fruit, vegetables, beef and hogs, grains, and excellent wine. Gardening and viticulture are carried on to some extent near the capital, though the markets of Madrid receive their most liberal supply of fruits and vegetables from Valencia. Sheep, goats, and horned cattle are reared, and fish are found in the Jarama and other rivers. Much timber is extracted from the forests of the northern and north-eastern parts of the province for building purposes and for firewood and charcoal. The royal domains of the Escorial, Aranjuez and El Pardo, and the preserves of the nobility, are all well wooded and contain much game. Efforts have also been made by the local authorities to cover the large stretches of waste ground and commons with pines and other trees.

The Sierra de Guadarrama has quarries of granite, lime and gypsum, and is known to contain iron, copper and argentiferous lead; but these resources are undeveloped. Other industries are chiefly confined to the capital; but cloth, leather, paper, earthenware, porcelain, glass, bricks and tiles, ironware, soap, candles, chocolate and lace are also manufactured on a small scale, and beyond Madrid there are beds of coal. There is very little commerce except for the supply of the capital, which is well served by rail and road.

Besides the local lines, all the great railways in the kingdom converge in this province, and it contains in all 221 m. of line. Besides Madrid, the towns of Aranjuez (12,679) and Alcalá de Henares (11,206) and the Escorial are described in separate articles. The other towns with more than 5000 inhabitants are Vallecas (10,128), Colmenar de Oreja (6182), Colmenar Viejo (2553) and Carabanchel Bajo (3562).

MADRID, the capital of Spain and of the province of Madrid, on the left bank of the river Manzanares, a right-hand tributary of the Jarama, which flows south into the Tagus. Pop. (1877), 397,816; (1887), 472,228; (1897), 512,150; (1900), 539,835. Madrid was the largest city in Spain in 1900; it is the see of an archbishop, the focus of the principal Spanish railways, the headquarters of an army corps, the seat of a university, the meeting-place of parliament, and the chief residence of the king, the court, and the captain-general of New Castile. It is, however, surpassed in ecclesiastical importance by Toledo and in commerce by Barcelona.

Situation and Climate.—Madrid is built on an elevated and undulating plateau of sand and clay, which is bounded on the north by the Sierra Guadarrama and merges on all other sides into the barren and treeless table-land of New Castile. Numerous water-courses (arroyos), dry except at rare intervals, is common, but there are others which flows into the Tagus. Pop. (1877), 397,816; (1887), 472,228; (1897), 512,150; (1900), 539,835. Madrid was the largest city in Spain in 1900; it is the see of an archbishop, the focus of the principal Spanish railways, the headquarters of an army corps, the seat of a university, the meeting-place of parliament, and the chief residence of the king, the court, and the captain-general of New Castile. It is, however, surpassed in ecclesiastical importance by Toledo and in commerce by Barcelona.

It is, however, surpassed in ecclesiastical importance by Toledo and in commerce by Barcelona.

Madrid has a very pleasant climate. The altitude of the city is 1370 ft. above sea-level. The climate is marked by a very rapid change in temperature; in the month of July, the mean temperature is 84°, and in the month of January, 34°, the mean temperature of these two months being 109°. The average temperature in the month of July is 78°, and in the month of January, 46°, the average temperature of these two months being 62°. The average temperature in the month of July is 78°, and in the month of January, 46°, the average temperature of these two months being 62°. The average temperature in the month of July is 78°, and in the month of January, 46°, the average temperature of these two months being 62°. The average temperature in the month of July is 78°, and in the month of January, 46°, the average temperature of these two months being 62°. The average temperature in the month of July is 78°, and in the month of January, 46°, the average temperature of these two months being 62°.
Drive to the race-course and the exhibition building. On the slopes of the other side of the Castellana, and along what were the northern limits of Madrid in 1875, the modern suburbs have extended to the vicinity of the fine cellular prison that was built at the close of the reign of King Alphonso XII, to replace the gloomy building known as El Saladero.

The new parts of the capital, with their broad streets and squares, and their villas sometimes surrounded with gardens, their boulevards lined by rather stunted trees, and their modern public buildings, all resemble the similar features of other European capitals, and contrast with the old Madrid that has preserved so many of its traits in architecture, popular life and habits. Some of the streets have been slightly widened, and in many thoroughfares new houses are being built among the ugly, irregular dwelling-places of the 18th and earlier centuries. This contrast is to be seen especially in and about the Calle Mayor, the Plaza Mayor, the Calle de Toledo, the Rastro, and the heart of the city.

Few capitals have more extensively developed their electric and horse tramways, gas and electric light installations and telephones. Much was done to improve the sanitary conditions of the city in the last twenty years of the 19th century. The streets are ploughed three times a day with fine-hose, but even that has little effect upon the rest of the city. The urbanization of the unhealthy suburbs is far from being final; for its abundance and purity, became wholly insufficient owing to the growth of the city. The old reservoir of the Laoloy canal, a cutting 32 m. long, and the additional reservoir opened in 1883, are quite insufficient for the needs of the modern Madrid, and were formerly kept in such an unsatisfactory state that for several months in 1898 and 1899 the water not only was on the point of giving out, but at times was of such inferior quality that the people had recourse to the many wells and springs of the city. The construction of new waterworks was delayed by a terrible accident, which occurred on the 8th of April 1905; the whole structure collapsed, and nearly 400 persons lost their lives in the flooded ruins. A decided improvement has been made in the burial customs of Madrid. No bodies are allowed to be interred in the churches and convents. Some of the older burial grounds in the northern suburbs have been closed altogether, and in those which remain open coffins are placed in niches in the arches. Of the old burial sites only that of San Ildelfonso remains in use.

The modern necropolis has been established a few miles to the north-east.

Principal Buildings.—As compared with other capitals Madrid has very few buildings of much architectural interest. The Basilica de Nuestra Senora de Atocha, on the Paseo de Atocha, a continuation of the Calle de Atocha, was originally founded in 1532. After being almost destroyed by the French, it was restored by Ferdinand VII., and rebuilt after 1806. The modern church is Romanesque in style; it contains a much venerated statue of the Virgin, attributed to St Luke. The collegiate church of San Isidro el Real, in the Calle de Toledo, dates from 1651; it has no architectural merit, but contains one or two valuable pictures and other works of art. It was originally owned by the Jesuits, but after their expulsion in 1769 it was reorganized and dedicated to St Isidore the Labourer (d. 1170), the patron saint of Madrid, whose remains were entombed here. When the diocese of Madrid was separated from that of Toledo San Isidro was chosen as the cathedral. The modern Gothic church of San Jeronimo el Real occupies a conspicuous site eastward of the town. The church of San Francisco el Grande, which contains many interesting monuments, is also known as the National Pantheon. An act was passed in 1837 declaring that the remains of all the most distinguished Spaniards should be buried here; but no attempt to enforce the act systematically was made until 1869, and even then the attempt failed. Towards the close of the 19th century the church was splendidly restored at the expense of the state. Its interior was decorated with paintings and statuary by some of the best masters of the day. The principal buildings unquestionably the most important is the royal palace (Palacio Real), on the west side of the town, on rising ground overlooking the Manzanares. It occupies the site of the ancient Moorish alcázar (citadel), where a hunting seat was built by Henry IV.; this was enlarged and improved by Charles V. when he first made Madrid his residence in 1532; it was further developed by Phillip II., but ultimately was destroyed by fire in 1734. The
present edifice was begun under Philip V. in 1737 by Sacchetti of Turin, and was finished in 1764. It is in the Tuscan style, and is 470 ft. square and 100 ft. in height, the material being white Colmenar granite, resembling marble. To the north of the palace are the royal stables and coach-houses, remarkable for their extent; to the south is the armory (Museo de la Real Armería), containing what is possibly the best collection of the kind in existence. After the Palacio Real may be mentioned the royal picture gallery (Real Museo de Pinturas), adjoining the Salon del Prado; it was built about 1783 for Charles III. by Juan de Villanueva as a museum of natural history and academy of sciences. It contains the collections of Charles V., Philip II. and Philip IV., and the pictures number upwards of two thousand. The specimens of Titian, Raphael, Tintoretto, Velazquez, Vandyck, Rubens and Teniers give it a claim to be considered the finest picture gallery in the world. The Biblioteca Nacional, in the Paseo de Recoletos, was founded by Philip V. in 1726. Not only the national library, with its important collections of MSS. and documents, but the archaeological museum, the museums of modern painting and sculpture, and the fine arts academy of San Fernando, are within its walls. The two houses of the Cortes meet in separate buildings. The deputies have a handsome building with a very valuable library in the Carrera San Jerónimo; the senators have an old Augustinian convent which contains some fine pictures. A large and handsome building near the Retiro Park contains the offices of the ministers of public works, agriculture and commerce, and of fine arts and education; nearly opposite stands the new station of the Southern Railway Company. The Great Northern and the Spain to Portugal Railway Companies have also replaced their old stations by very spacious, handsome structures, much resembling those of Paris. In 1856 the Royal Exchange was installed in a large monumental building with a fine colonnade facing the Paseo del Prado, the largest monument, not far from the museum of paintings.

Of the promenades and open places of public resort the most fashionable and most frequented is the Prado (Paseo del Prado, Salon del Prado) on the east side of the town, with its northward continuation—the Paseo de Recoletos. To the south of the town is the Paseo de las Delicias, and on the west, below the royal palace, and skirting the Manzanares, is the Paseo de la Vírgen del Puerto, used chiefly by the poorer classes. Eastward from the Prado are the Buen Retiro Gardens, with ponds and pavilions, and a menagerie. The gardens were formerly the grounds surrounding a royal hunting seat, on the site of which a palace was built for Philip IV. in 1633; it was destroyed during the French occupation.

Education, Religion and Charity.—Madrid University was an old gild of the College de la Universidad, founded in 1350 by Alphonso Orozco. Schools of mathematics and natural science were added in the 16th and 17th centuries, and in 1766 the medical and surgical college of San Carlos was opened. In 1836-1837 the University of Alcalá de Henares (q.v.) was transferred to the capital and the older foundations incorporated with it. The University of Madrid thenceforth became the headquarters of education in central Spain. It has an observatory, and a library containing more than 2,000,000 printed books and about 3500 MSS. It gives instruction, chiefly in law and medicine, but also in literature, philosophy, mathematics and physics, to about 5000 students. Associated with the university is the preparatory school of San Isidro, founded by Philip IV. (1621-1665), and reorganized by Charles III. in 1770.

There are upwards of 100 official primary schools and a large number of gymnasia, and also with the schools operated by the Jesuits and the Scolian fathers, a special mention. Madrid also has schools of agriculture, architecture, civil and mining engineering, the fine arts, veterinary science and music. The school of military and naval education is also for the town. At the central schools there are a self-supporting institute for preparing girls for the higher degrees and for certificates as primary teachers, and an institute for secondary education, conducted chiefly by ecclesiastics. Among the educational foundations may be reckoned the real garden, dating from 1781, the libraries of the palace, the university, and San Isidro, and the museum of natural science, exceedingly rich in the mineralogical department. The principal learned society is the royal Spanish Academy, founded in 1713 for the cultivation and improvement of the Spanish tongue. The Academy of History possesses a good library, rich in MSS. and incunabula, as well as a large collection of coins and medals of men of letters, of fine arts, the exact sciences, moral and political science, medicine and surgery, and jurisprudence and legislation, all of which possess libraries, there are also anthropological, economic and geographical societies. Madrid has a large cemetery opened in 1853, when the older Protestant cemetery in the Paseo de Recoletos was closed. The town also contains a British embassy chapel, a German chapel, and several Spanish clerical chapels, attended by over 1200 native Protestants, while the Protestant schools, chiefly supported by British, German and American contributions, are attended by more than 2500 students. The first Protestant bishop of Madrid was consecrated in 1895 by the Bishop of the Diocese of the Panteón. The charities have greatly improved between 1885 and 1905. The Princely Hospital was completely restored on modern methods, and can accommodate several hundred patients. The old contagious diseases hospital of San Juan de Dios was pulled down and a fine new hospital built in the suburbs beyond the Retiro Park, to hold 700 patients. The military hospital was demolished and a very good one built in the suburbs. There are in all twenty hospitals in Madrid, and a lunatic asylum on the outskirts of the capital, founded by one of the most eminent of Spanish surgeons, and admirably conducted. New buildings have been provided for the orphanages, and for the asylums for the blind, deaf and dumb, incurables and aged paupers. There are a large number of voluntary charities, including a sugar factory; these are old and well-endowed foundations. Public charity generally is very active. In Madrid, as in the rest of Spain, there has been an unprecedented increase in convents, monasteries and religious foundations, societies and Roman Catholic workmen's clubs and classes.

Apart from private institutions for such purposes, the state maintains in the capital a savings bank for the poorer classes, and a poor house for the old and infirm. The associations of local industries are organized in guilds, which themselves collect the lump sum of taxation exacted by the exchequer and the municipality from each promio or class of taxpayers. The working classes also have commercial and industrial clubs or circles that are obeyed by the guild with great espírit de corps, a chamber of commerce and industries, and "associations of productions" for the defence of economic interests.

Industries.—The industries of the capital have developed extraordinarily since 1890. In the town, and within the municipal boundaries in the suburbs, many manufactories have been established, giving employment to more than 30,000 hands, besides the 4,000 women and girls of the Tobacco Monopoly Company's factory. Among the most important factories are those which make every article in leather, especially cigar and card cases, purses and pocket-books. Next come the manufactories of fans, umbrellas, sunshades, chemicals, varnishes, buttons, wax candles, beds, cardboard, porcelain, coarse pottery, matches, baskets, sweets and preserves, gloves, guitars, biscuits, funnels, umbrellas, forks, cards, cottons, jewelry, banks of all kinds, plate and plated goods. There are also tanneries, saw and flour mills, glass and porcelain works, soap works, brickfields, paper mills, zinc, bronze, copper and iron foundries. The working classes are strongly imbued with socialist ideas. Strikes and May Day demonstrations have often been troublesome. Order is kept by a garrison of 12,500 men in the barracks of the town and cantonments around, and by a strong force of civil guards or gendarmes quartered in the town itself. The civil and municipal authorities can employ beside the gendarmes the police, about 1400 strong, and what is called the guardias urbanos, another police force whose special duty it is to regulate the street traffic and prevent breaches of the municipal regulations. There is not, on the average, more crime in Madrid than in the provinces.

History.—Spanish archaeologists have frequently claimed for Madrid a very high antiquity, but the earliest authentic historical mention of the town (Majrit, Majoritum) occurs in the Arab chronicle, and does not take us farther back than to the first half of the 10th century. The place was finally taken from the Moors by Alphonso VI. (1083), and was made a hunting-seat by Henry IV., but first rose into importance when Charles V., benefiting by its keen air, made it his occasional residence. Philip II. created it his capital and "only court" (única corte) in 1560. It is, however, only classed as a town (villa), having
never received the title of city (ciudad). Fruitless attempts were made by Philip III. and Charles III. respectively to transfer the seat of government to Valladolid and to Seville. (See also SPANISH: History.)

MADRIGAL (Ital. madrigale), the name of a form of verse, the exact nature of which has never been decided in English, and of a form of vocal music.

(1) In Verse.—The definition given in the New English Dictionary, "a short lyrical poem of amatory character," offers no distinctive formula; some madrigals are long, and many have nothing whatever to do with love. The most important English collection of madrigals, not set to music, was published by William Drummond of Hawthornden (1585-1649) in his Poems of 1616. Perhaps the best way of ascertaining what was looked upon in the 17th century as a madrigal is to quote one of Drummond's:

The beauty and the life
Of life's and beauty's fairest paragon,
O tears! O grief! hung at a feeble thread,
To which pale Atropos had set her knife;
The soul with many a groan
Had left me backward part,
And now did take his last leaf of the heart;
Nought else did want, save death, even to be dead;
When the afflicted band about her bed,
Seeing so fair him come in lips, eyes, eyes,
Cried ah! and can death enter Paradise?

This may be taken as a type of Drummond's madrigals, of which he has left us about eighty. They are serious, brief, irregular lyrics, in which neither the amatory nor the complimentary tone is by any means obligatory. Some of these pieces contain as few as six lines, one as many as fourteen, but they average from nine to eleven. In the majority of examples the little poem opens with a line of six syllables, and no line extends beyond ten syllables. The madrigal appears to be a short canzone of the Tuscan type, but less rigidly constructed. In French the madrigal has not this Italian character. It is simply a short piece of verse, ingenious in its turn and of a gallant tendency. The idea of compliment is essential. J. F. Guichard (1730-1811) writes:

Orgen, poète marial,
À Venus compare sa femme;
C'est pour la belle un madrigal,
C'est pour Venus une épigramme.

This quatrain emphasizes the fact that in French a madrigal is a trifling piece of erotic compliment, neatly turned but not seriously meant. The credit of inventing the old French verse-form of madrigal belongs to Clément Marot, and one of his may be quoted in contrast to that of Drummond—

Un doux nomi avec un doux sourire
Est tant bonnetiste, il le vous faut apprendre;
Quant est de oui, si veniez à le dire,
D'avoir trop dit je voudrais vous reprendre;
Non que je sois emmuyé d'entreprendre
D'avoir le fruit dont le désir me point;
Mais je voudrais qu'en ne le laissant prendre,
Vous me disez: vous ne l'auriez point.

In English, when the word first occurred—it has not been traced farther back than 1588 (in the preface to Nicholas Yonge's Musica transalpina)—it was identified with the chief form of secular vocal music in the 16th century. In 1741 John Immyns (d. 1764) founded the Madrigal Society, which met in an ale-house in Bride Lane, Fleet Street; this association still exists, and is the oldest musical society in England. The word "madrigal" is frequently also used to designate a sentimental or trifling expression in a half-contemptuous sense.

(2) In Music.—As a definite musical art-form, the madrigal was known in the Netherlands by the middle of the 15th century; like the motet, it obviously originated in the treatment of counterpoint on a canto fermo, some early examples even combining an ecclesiastical canto fermo in the tenor with secular counterpoint in the other parts. Thus Josquin's Déploration de Jehan Ockenheim (see Musici: Ms 8004) might equally well be called a madrigal or motet, if the word "madrigal" were used for compositions to French texts at all. But by the middle of the 16th century the Italian supremacy in music had developed the madrigal into the greatest of secular musical forms, and made it independent of the form of the words; and thus when Lasso sets Marot's madrigals to appropriately witty and tuneful music he calls the result a "chanson"; while when Palestrina composes Petrarca's Sonnets to the Virgin in memory of Laura, the result appears as a volume of Madrigals spirituali. Elégics madrigals, whether spiritual or secular, were thus as common as any other kind; so that when the Musica transalpina brought the word "madrigal" to England it brought a precedent for the poet Drummond's melancholy type of madrigal poetry.

Italian madrigals, however, are by no means always elegiac; but the term always means a highly organized and flowing polyphonic piece, often as developed as the motet, though, in the mature classical period, distinct in style. Yet masses were often found on the themes of madrigals, just as they were on the themes of motets (see MASS; MOTET); and it is interesting, in such beautiful cases as Palestrina's Missa gia fu chi 'm ebbe cara, to detect the slight strain the mildly scandalous origin of the themes puts upon the ecclesiastical style.

The breaking strain was put on the madrigal style at the end of the 16th century, in one way by the new discords of Monteverde and (with more musical invention) Schütz; and in another way by the brilliant musical character-drawing of Vecchi, whose Amfà frarnasso is a veritable comic opera in the form of a set of fourteen madrigals, all riotously witty in the purest and most masterly polyphonic style. It was probably meant, or at least made use of, to laugh down the earliest pioneers of opera (q.c.); hence it is the beginning of the end for the madrigal as a living art. Long afterwards we occasionally meet with the word again, when a 17th or 18th century composer sets to some kind of accompanying singing a poem of madrigalesque character. But this does not indicate any continuation of the true musical history of the madrigal. The strict meaning of the word in its musical sense is, then, a musical setting of an Italian or English non-ecclesiastical poem (typically a canzone) for unaccompanied chorus, in a 16th-century style less ecclesiastical than the motet, but as like it in organization as the form and sentiment of the words admit. The greatest classics in the madrigal style are those of Italy; and but little, if at all, below them come the English. The form, though not the name, of course, exists in the 16th-century music of other languages whenever the poetry is not too light for it.

It is important but easy to distinguish the madrigal from the lighter 16th-century forms, such as the Italian villanella and the English ballad, these being very homophonic and distinguished by a strong lift of their rhythm.

The madrigal has been very successfully revived in modern English music with a more or less strict adherence to the 16th century principles; the compositions of De Pearsall being of high artistic merit, while the Madrigale spirituale in Stanford's oratorio Eden is a movement of rare beauty.

(D. F. T.)

MADURA (Dutch Modoroa), an island of the Dutch East Indies, separated by the shallow Strait of Madura from the N.E. coast of Java. Pop. (1897), 1,652,580, of whom 1,646,071 were natives, 4,252 Chinese and 558 Europeans. It extends from about 112° 32' to 114° 7' E., and is divided into two nearly equal portions by the parallel of 5° S.; the area is estimated at 1725 sq. m. It is a plateau-like prolongation of the limestone range of northern Java, with hills (1300 to 1600 ft. high) and dales. The formation of the coast and plains is Tertiary and recent alluvium. Hot springs are not infrequent; and in the valley between Gunong Geger and Banjar lies the mud volcano of
MADURA—MAECENAS

Banju Ening. The coasts are clothed with tropical vegetation; but the soil is better fitted for pastoral than agricultural purposes. Fishing and cattle-rearing are the chief means of subsistence. Besides rice and maize, Madura yields coco-nut oil and jati. The manufacture of salt for the government, abolished in other places, continues in Madura. Hence perhaps the name is derived (Sansk., mandura, salt). Petroleum is found in small quantities.

The principal town is Sumenep; and there are populous Malay, Arab and Chinese villages between the town and the European settlement of Maringan. On a hill in the neighbourhood lies Asta, the burial-place of the Sumenep princes. Pamekasan is the seat of government. Bangkang is a large town with the old palace of the sultan of Madura and the residences of the princes of the blood; the mosque is adorned with the first three suras of the Koran, thus differing from nearly all the mosques in Java and Madura, though resembling those of western Islam. In the vicinity once stood the Erprins fort. Aribaya (less correctly Arosbaya) is the place where the first mosque was built in Madura, and where the Dutch sailors first made acquaintance with the natives. The once excellent harbour is now silted up. Sampang is the seat of an important market. The Kangean and Sapu islands, belonging to Madura, yield timber, trepan, turmeric, and coffee.

Madura formerly consisted of three native states—Madura or Bangkang, Pamekasan and Sumenep. The whole island was considered part of the Java residency of Surabaya. The separate residency of Madura was constituted in 1857; it now consists of four “departments”—Pamekasan, Madura, Sumenep and Sampang.

MADURA, a city and district of British India, in the Madras Presidency. The city is situated on the right bank of the river Vaigai, and has a station on the South Indian railway 345 m. S.E. of Madras. Pop. (1901), 105,684. The city was the capital of the old Pandyan dynasty, which ruled over this part of India from the 5th century B.C. to the end of the 11th century A.D. Its great temple forms a parallelogram about 847 ft. by 729 ft., and is surrounded by nine ghopuras, of which the largest is 38 ft. high. Below ornamental pyramids begin with step-posts of single stones 60 ft. in height, and rise course upon course, carved with rows of gods and goddesses, peacocks, bulls, elephants, horses, lions, and a bewildering entanglement of symmetrical ornament all coloured and gilded, diminishing with distance until the stone trisul at the top looks like the finest jeweller's work. The temple, which contains some of the finest carving in southern India, is said to have been built in the reign of Viswanath, first ruler of the Nayak dynasty. Its chief feature is the sculptured “Hall of a Thousand Pillars.” The palace of Tirumala Nayak is the most perfect relic of secular architecture in Madras. This palace, which covers a large area of ground, has been restored, and is utilized for public offices. The Vasantha, a hall 333 ft. long, probably dedicated to the god Sundareswara, and the Tamakam, a pleasure-palace, now the residence of the collector, are the other principal buildings of this period.

The last of the old Pandyan kings is said to have exterminated the Jains and conquered the neighbouring kingdom of Chola; but he was in his turn overthrown by an invader from the north, conjectured to have been a Mahommedan. In 1324 a Moslem army under Malik Kafur occupied Madura, and the Hindus were held in subjection for a period of fifty years. Subsequently Madura became a province of the Hindu Empire of Vijayanagar. In the middle of the 16th century the governor Viswanath established the Nayak dynasty, which lasted for a century. The greatest of the line was Tirumala Nayak (reigned 1623–1659), whose military exploits are recorded in the contemporary letters of the Jesuit missionaries. He adored Madura with many public buildings, and extended his empire over the adjoining districts of Tinnevelly, Travancore, Coimbatore, Salem and Trichinopoly. His reputation of the nominal allegiance paid to the raja of Vijayanagar brought him into collision with the sultan of Bijapur, and after a lapse of three centuries Mahommedans again invaded Madura and compelled him to pay them tribute. After the death of Tirumala the kingdom of Madura gradually fell to pieces, being invaded by both Mahommedans and Marathas. About 1736 the district fell into the hands of the nawab of the Carnatic, and the line of the Nayaks was extinguished. About 1764 British officers took charge of Madura in trust for Mahommed Ali (Wallah Jah), last independent nawab of the Carnatic, whose son finally ceded his rights of sovereignty to the East India Company in 1801.

The DISTRICT of Madura has an area of 8701 sq. m. Pop. (1901), 2,831,280, an increase of 8-5% in the decade. It consists of a section of the plain stretching from the mountains east to the sea, coinciding with the basin of the Vaigai river, and gradually sloping to the S.E. The plain is broken by the outlying spurs of the Ghats, and by a few isolated hills and masses of rock scattered over the country. The most important spur of the Ghats is known as the Palni hills, which project E.N.E. across the district for a distance of about 54 m. Their highest peaks are more than 8000 ft. above sea-level, and they enclose a plateau of about 100 sq. m., with an average height of 7000 ft. On this plateau is a great salt-mining region, and Koyam, a large coffee-planting is successfully carried on. The other principal crops of the district are millets, rice, other food-grains, oil-seeds and cotton. Tobacco is grown chiefly in the neighbourhood of Dindigul, whence it is exported to Trichinopoly, to be made into cigars. There are several cigar factories and a number of salt-petre refineries. The only other large industry is that of coffee-cleaning. Madura is traversed by the main line of the South Indian railway. It has four small seaports, whose trade is chiefly carried on with Ceylon. The most important irrigation work, known as the Periyar project, consists of a tunnel through the Travancore hills, to convey the rainfall across the watershed. See Madura District Gazetteer (Madras, 1906).

MADVIG, JOHAN NICOLAI (1804–1886), Danish philologist, was born on the island of Bornholm, on the 7th of August 1804. He was educated at the classical school of Frederiksborg and the university of Copenhagen. In 1828 he became reader, and in 1829 professor, of Latin language and literature at Copenhagen, and in 1832 was appointed university librarian. In 1848 Madvig entered parliament as a member of the Danish party named the Eider-Danish party, because they desired the Eider to be the boundary of the country. When this party came into power Madvig became minister of education. In 1852 he became director of public instruction. Some years later, from 1856 to 1863, Madvig was president of the Danish parliament and leader of the National Liberal party. With these brief interruptions the greater part of his life was devoted to the study and teaching of Latin and the improvement of the classical schools, of which he was chief inspector. As a critic he was distinguished for learning and acumen. He devoted much attention to Cicero, and revolutionized the study of his philosophical writings by an edition of De Finibus (1830; 3rd ed., 1876). Perhaps his most widely known works are those on Latin grammar and Greek syntax, especially his Latin grammar for schools (Eng. trans. by G. Woods). In 1874 his sight began to fail, and he was forced to give up much of his work. He still, however, continued to publish and in 1879 he was chosen rector for the sixth time. In 1880 he resigned his professorship, but went on with his work on the Roman constitution, which was completed and published before his death. In this book Madvig takes a strongly conservative standpoint and attacks Mommsen's views on Caesar's programme of reforms. It is a clear exposition, though rather dogmatic and without sufficient regard for the views of other scholars. His last work was his autobiography, Lisserindringer (published 1887). Madvig died at Copenhagen on the 12th of December 1886.

See J. E. Sandys, History of Classical Scholarship (1908), iii., 319–324.

MAECENAS, GAIUS (CILNIUS), Roman patron of letters, was probably born between 74 and 64 B.C., perhaps at Arretium. Expressions in Propertius (ii. 1, 25–30) seem to imply that he...
had taken some part in the campaigns of Mutina, Philippi and Perusia. He prided himself on his ancient Etruscan lineage, and claimed descent from the princely house of the Cilini, who excited the jealousy of their townsman by their preponderating wealth and influence at Arretium in the 4th century B.C. (Livy, x. 3). The Galus Maecenas mentioned in Cicero (Pro Cluentio, 56) as an influential member of the equestrian order in 91 B.C. may have been his grandfather, or even his father. The testimony of Horace (Odes iii. 8, 5) and Maecenas's own literary tastes imply that he had profited by the highest education of his time. His great wealth may have been in part hereditary, but he owed his position and influence to his close connexion with the emperor Augustus. He first appears in history in 40 B.C., when he was employed by Octavian in arranging his marriage with Scribonia, and afterwards in assisting to negotiate the peace of Brundusium and the reconciliation with Antony. It was in 39 B.C. that Horace was introduced to Maecenas, who had before this received Varus and Virgil into his intimacy. In the "Journey to Brundusium," (Horace, Satires, i. 5) in 37, Maecenas and Cocceius Nerva are described as having been sent on an important mission, and they were successful in patching up, by the Treaty of Tarentum, a reconciliation between the two claimants for supreme power. During the Sicilian war against Sextus Pompeius in 36, Maecenas was sent back to Rome, and was entrusted with supreme administrative control in the city and in Italy. He was vice-gerent of Octavian during the campaign of Actium, when, with great promptness and secrecy, he crushed the conspiracy of the younger Lepidus; and during the subsequent absences of his chief in the provinces he again held the same position. During the latter years of his life he fell somewhat out of favour with his master. Suetonius (Augustus, 66) attributes the loss of the imperial favour to Maecenas having indiscreetly revealed to Terentia, his wife, the discovery of the conspiracy in which her brother Murena was implicated. But according to Dio Cassius (liv. 19) it was due to the emperor's relations with Terentia. Maecenas died in 8 B.C., leaving the emperor heir to his wealth.

Opinions were much divided in ancient times as to the personal character of Maecenas; but the testimony as to his administrative and diplomatic ability was unanimous. He enjoyed the credit of sharing largely in the establishment of the new order of things, of reconciling parties, and of carrying the new empire safely through many dangers. To his influence especially was attributed the humaner policy of Octavian after his first alliance with Antony and Lepidus. The best summary of his character as a man and a statesman is that of Velleius Paterculus (i. 88), who describes him as "of sleepless vigilance in critical emergencies, far-seeing and knowing how to act, but in his relaxation from business more luxurious and effeminate than a woman."

Expressions in the Odes of Horace (ii. 17, 1) seem to imply that Maecenas was deficient in the rhetorical and critic characteristics of the Augustan Age. His character as a munificent patron of literature—which has made his name a household word—is gratefully acknowledged by the recipients of it and attested by the regrets of the men of letters of a later age, expressed by Martial and Juvenal. His patronage was exercised, not from vanity or a mere dilettante love of letters, but with a view to the higher interest of the state. He recognized in the genius of the poets of that time, not only the truest ornament of the court, but a power of reconciling men's minds to the new order of things, and of investing the actual state of affairs with an ideal glory and majesty. The change in seriousness of purpose between the Elogia and the Georgics of Virgil was in a great measure the result of the direction given by the statesman to the poet's genius. A similar change between the earlier odes of Horace, in which he declares his epicurean indifference to affairs of state, and the great national odes of the third book is to be ascribed to the same guidance. Maecenas endeavoured also to divert the less masculine genius of Propertius from harping continually on his love to themes of public interest. But if the motive of his patronage had been merely political it never could have inspired the affectation which it did in its recipients. The great charm of Maecenas in his relation to the men of genius who formed his circle was his simplicity, cordiality and sincerity. Although not particular in the choice of some of the associates of his pleasures, he admitted none but men of worth to his intimacy, and when once admitted they were treated like equals. Much of the wisdom of Maecenas probably lives in the Satires and Epistles of Horace. It has fallen to the lot of no other patron of literature to have his name associated with works of such lasting interest as the Georgics of Virgil, the first three books of Horace's Odes, and the first book of his Epistles.

Maecenas himself wrote in both prose and verse. The few fragments that remain show that he was less successful as an author than as a judge and patron of literature. His prose works on various subjects—Prometheus, Symposium (a banquet at which Virgil, Horace and Messalla were present), De cultu suo (on his manner of life)—were ridiculed by Augustus, Seneca and Quintilian for their strange style, the use of rare words and awkward transpositions. According to Dio Cassius, Maecenas was the inventor of a system of shorthand.

There is no good modern biography of Maecenas. The best known is that by P. S. Frandsen (1843). See "Horace et Mécène" by J. Girard, in La Revue politique et litteraire (Dec. 27, 1873); V. J. Augustin, in modern vii, (1872); ii. 432 seq. (1879), and J. G. Augustin, in J. M. C. Scholaires, Dio Cassius, Tacitus (Annals), Suetonius (Augustus). The fragments have been collected and edited by F. Harde (1889).

MAECIANS, LUCIUS VOLUSIUS (2nd cent.). Roman jurist, was the tutor in law of the emperor Marcus Aurelius. When governor of Alexandria he was slain by the soldiers, as having participated in the rebellion of Avidius Cassius (175). Maecianus was the author of works on trusts (Fideicommissae), on the Admissibility, and of a collection of the Rhodian laws relating to maritime affairs. His treatise on numerical divisions, weights and measures (Distributio) is extant, with the exception of the concluding portion.

See Capitullus, Antoninus, 3; Vulcacius Gallicus, Avidius Cassius, 7; edition of the metrical work by F. Hultsch in Mechanicalorum scriptorum religiae, ii. (1860); Mommsen in Abhandlungen der österreichischen Gesellschaft der Wissenschaften, iii. (1853).

MAELDUIN (or MAELDAIN), VOYAGE OF (Imram Maelduin), an early Irish romance. The text exists in an 11th-century redaction, by certain Aed the Fair, described as the "chief sage of Ireland," but it may be gathered from internal evidence that the tale itself dates back to the 8th century. It belongs to the group of Irish romance, the Navigations (Imrama), the common type of which was probably imitated from the classical tales of the wanderings of Jason, of Ulysses and of Aeneas. Maelduin, the foster-son of an Irish queen, learnt on reaching manhood that he was the son of a nun, and that his father, Ailill of the edge of battle, had been slain by a marauder from Leix. He set sail to seek his father's murderer, taking with him a fellow-captive of the sorcerer, seventeen men. His three foster-brothers swam after him, and were taken on board. This increase of the fateful number caused Maelduin's vengeance to be deferred for three years and seven months, until the last of the intruders had perished. The travellers visited many strange islands, and met with a long series of adventures, some of which are familiar from other sources. The Voyage of St Brendan (q.v.) has very close similarities with the Maelduin, of which it is possibly a clerical imitation, with the important addition of the whole-island episode, which it has in common with "Sindbad the Sailor."

Imram Corair Mauduin is preserved, in each case imperfectly, in the Lebrin na Udhe, a MS. in the Royal Irish Academy, Dublin; the Library of Trinity College, Dublin; fragments are in Harleian MS. 3280 and Egerton MS. 1782 in the British Museum. There are translations by Patrick Joyce, Old Celtic Romances (1879), by Whitley Stokes (a more critical version, printed together with the text) in Revue Celtique, vols. i. and x. (1888-1889). See H. Zimmer, "Brendan's Meerfahrt" in Zeitschrift für deutsches Altertum, vol. xxxiii. (1889). Tennyson's Voyage of Maelduin, suggested by the Irish romance, borrows little more than its framework.
MAELIUS, SPURIUS (d. 430 B.C.), a wealthy Roman plebeian, who during a severe famine bought up a large amount of corn and sold it at a low price to the people. Lucius (or Gaius) Minucius, the patrician profectus annonae (president of the market), therupon accused him of courting popularity with a view to making himself king. The cry was taken up. Maelius, summoned before the aged Cincinnatus (specialy appointed dictator), refused to appear, and was slain by Gaius Servilius Ahala; his house was razed to the ground, his corn distributed amongst the people, and his property confiscated. The open space called Aequaemiaulium, on which his house had stood, preserved the memory of his death. Cicero calls Ahala's deed a glorious one, but, whether Maelius entertained any ambitious projects or not, his summary execution was an act of murder, since by the Valerio-Horatian laws the dictator was bound to allow the right of appeal.

See Niebuhr's History of Rome, ii. 418 (Eng. trans., 1851); G. Cornewall Lewis, Credibility of early Roman History, ii., Livy, iv. 143; Cicero, De senectute 16, De amicitia 8, De republica, ii. 27; Florus, i. 26; Dion. Halic. xii. 1.

MAELSTROM (whirlpool), a term originally applied to a strong current running past the south end of the island of Moskenaes, a member of the group of Lofoten Islands on the west coast of Norway. It is known also as the Moskenstrom. Though dangerous in certain states of wind and tide, the tales of ships being swallowed in this whirlpool are fables. The word is probably of Dutch origin, from maal, to grind or whirl, and ström or stroom, a stream or current. It appears on Mercator's Atlas, 1595.

MAENADS (Gr. Μαιανδροί, frenzied women), the female attendants of Dionysus. They are known by other names—Bacchae, Thyiaxes, Clodonex and Mimallones (the last two probably of Thracian origin)—all more or less synonymous.

See the exhaustive articles by A. Legrand in Darenberg and Saglio's Dictionnaire des antiquités and A. Rapp in Roscher's Lexicon der Mythologie; also editions of Euripides, Bacchae (e.g., J. E. Sandys).

MAENIUS, GAUCIUS, Roman statesman and general. Having completed (when consul in 338 B.C.) the subjugation of Latium, which with Campania had revolted against Rome, he was honoured by a triumph, and a column was erected to him in the Forum. When censor in 328, in order that the spectators might have more room for seeing the games that were celebrated in the Forum, he provided the inhabitants of the neighbourhood with balconies, which were called after him maciniae.

See Festus, s.v. Maeniana; Livy viii. 13, ix. 34; Pliny, Nat. Hist. xxxiv. 11 (5).

MAELRANT, JACOB VAN (c. 1235–c. 1300), Flemish poet, was born in the Frans de Burghes (tradition says at Damme) between 1230 and 1240. He was sacristan of Maelrant, in the island of Ost-Voorne, and afterwards clerk to the magistrates at Damme. His early works are translations of French romances. Maelrant's most serious work in the field of romance was his Vistorien von Troyen (c. 1264), a poem of some forty thousand lines, translated and amplified from the Roman de Troie of Benoît de Sainte-More. From this time Maelrant rejected romance as idle, and devoted himself to writing scientific and historical works for the education and enlightenment of the Flemish people. His Heimelichedt der Heimeltchelen (c. 1266) is a translation of the Secretas secretorum, a manual for the education of princes, ascribed throughout the middle ages to Aristotle. Van der Natuurn Bloemen is a free translation of De natura rerum, a natural history in twenty books by a native of Brabant, Thomas de Cantimpré; and his Rijmbijbel is taken, with many omissions and additions, from the Historia scholastica of Petrus Comestor. He supplemented this metrical paraphrase of Scripture history by Die Wrake van Jherusalem (1271) from Josephus. Although Maelrant was an orthodox Catholic, he is said to have been called to account by the priests for translating the Bible into the vulgar tongue. In 1284 he began his magnum opus, the Spiegel historiael, a history of the world, derived chiefly from the third part of the Speculum majus of Vincent de Beauvais. This work was completed by two other writers, Philip van Utenbroek and Lodowijk van Veithem. Maelrant died in the closing years of the 13th century, his last poem being Stenen van den lande van oversee, dating from 1291. The greater part of his work consists of translations, but he also produced poems which prove him to have had real original poetic faculty. Among these are Die Clausuile van der Bibel, Der Kerken Claze, imitated from the Complaines of Rutebeuf, and the three dialogues entitled Martijin, in which the fundamental questions of theology and ethics were discussed. In spite of his orthodoxy, Maelrant was a keen satirist of the corruptions of the clergy. He was one of the most learned men of his age, and for two centuries was the most celebrated of Flemish poets.

Vordam.

MAES, NICOLAS (1612–1693), Dutch painter, was born at Dordrecht, and went about 1650 to Amsterdam, where he entered Rembrandt's studio. Before his return to Dordrecht in 1654 Maes painted a few Rembrandesque genre pictures, with life-size figures and in a deep glowing scheme of colour, like the "Reverie" at the Ryks Museum in Amsterdam, the "Card Players" at the National Gallery, and the "Children with a Goat Carriage," belonging to Baroness N. de Rothschild. So closely did his early style resemble that of Rembrandt, that the last-named picture, and other canvases in the Leipzig and Budapest galleries and in the collection of Lord Radnor, were or are still ascribed to Rembrandt. In his best period, from 1655 to 1665, Maes devoted himself to domestic genre on a smaller scale, retaining to a great extent the magic of colour he had learnt from Rembrandt. Only on rare occasions did he treat scriptural subjects, as in the earl of Denbigh's "Hagar's Departure," which has been ascribed to Rembrandt. His drawings were bought by Van Dyck, Sweerts, Rembrandt, or preparing a meal. In 1665 he went to Antwerp, where he remained till 1678, in which year he probably returned to Amsterdam. His Antwerp period coincides with a complete change in style and subject. He devoted himself almost exclusively to portraiture, and abandoned the intimacy and glowing colour harmonies of his earlier work for a careless elegance which suggests the influence of Van Dyck. So great indeed was the change, that it gave rise to the theory of the existence of another Maes, of Brussels. Maes is well represented at the National Gallery by five paintings: "The Cradle," "The Dutch Housewife," "The Idle Servant," "The Card Players," and a man's portrait. At Amsterdam, besides the splendid examples to be found at the Ryks Museum, is the "Inquisitive Servant" of the Six collection. At Buckingham Palace is The Listening Girl (repetitions exist), and at Apsley House "Selling Milk" and "The Listener." Other notable examples are in the Berlin, Brussels, St Peterburg, the Hague, Frankfort, Hanover and Munich galleries.

MAESTRO, a north-westerly wind observed in the Adriatic and surrounding regions, chiefly during summer. The maestro is a "fine weather" wind, and is the counterpart of the sirocco.

MAETERLINCK, MAURICE (1862–), Belgian-French dramatist and poet, of Flemish extraction, was born at Ghent on the 29th of August 1862. He was educated at the Collège Sainte-Barbe, and then at the university of his native city, where, at the age of twenty-four, he was enrolled as a barrister. In 1887 he settled in Paris, where he immediately became acquainted with Villiers de l'Isle-Adam and the leaders of the symbolist school of French poetry. At the death of his father, Maeterlinck returned to Belgium, where he thenceforth mainly resided: in the winter at Ghent, in the summer on an
estate at Oostacker. He had by this time determined to devote his whole life to poetry, a dedication which his fortune permitted. His career as an author began in 1889, when he published a volume of verse, *Serres chaudes*, and a play, *La Princesse Maleine*, the latter originally composed in metre, but afterward carefully rewritten in prose, the vehicle which the author continued to use for his dramatic work. Maeterlinck was at this time totally unknown, but he became famous through an article by Octave Mirbeau, prominently published in the *Paris Figaro*, entitled "A Belgian Shakespeare." The enthusiasm of this review and the excellence of the passages quoted combined to make Maeterlinck the talk of the town. Maeterlinck, among his Belgian roots, continued to work with extreme deliberation. In 1890 he published, in Brussels, two more plays, *L'Enescul* and *Les Aveugles;* followed in 1891 by *Le Sept princesses*. His strong leaning to mysticism was now explained, or defined, by a translation of the Flemish-medieval visionary, the Admirable Ruyshroeck, which Maeterlinck brought out in 1892. It is 1893 that appeared what has been perhaps the most successful of all his plays on the stage, *Pelléas et Mélisande*, followed in 1894 by those very curious and powerful little dramas written to be performed by marionettes: *Allodine et Polomides, Intérieur* and *Le Mort de Tintagiles*. In 1895 Maeterlinck brought out, under the title of *Annabella*, a translation of Ford's *'Tis Pity She's a Whore*, with a preface. Two philosophical works followed, a study on Novalis (1893) and *Le Trésor des humbles* (1896). In 1896 he returned to drama with *Aglavaine et Sélyslette* and to lyric verse with *Douze chansons*. A monograph on the ethics of mysticism, entitled *La Sagesse et la destinée*, was issued, as a kind of commentary on his own dramas, in 1898; and in 1901 Maeterlinck produced a fascinating volume of prose, founded upon observations made in his apiaries at Oostacker, in which philosophy, fancy and natural history were surprisingly mingled—*La Vie des abeilles*. In 1902 he published *Le Temple ensorcel* and *Mamma Vanna*; in 1903 *Joycelle*. In 1901 he began to issue, in Brussels, an edition of his complete dramatic works.

The nature of Maeterlinck's writings, whether in prose or verse, has been strictly homogeneous. Few poets have kept so rigorously to a certain defined direction in the practice of their art. Whether in philosophy, or drama, or lyric, Maeterlinck is exclusively occupied in revealing, or indicating, the mystery which lies, only just out of sight, beneath the surface of ordinary life. In order to produce this effect of the mysterious he aims at an extreme simplicity of diction, and a symbolism so realistic as to be almost bare. He allows life itself to astonish us by its strangeness, by its inexplicable elements. Many of his plays are really highly pathetic records of unseen emotion; they are occupied with the spiritual adventures of souls, and the ordinary facts of time and space have no influence upon the movements of the characters. We know not who these orphan princesses, these blind persons, these pale Arthurian knights, these aged guardians of desolate castles, may be; we are not informed whence they come, nor whither they go; there is nothing concrete or circumstantial about them. Their life is intense and consistent, but it is wholly of a spiritual character; they are mysterious with the mystery of the movements of a soul. These characteristics, which make the dramatic work of Maeterlinck so curious and unique, are familiar to most readers in *Pelléas et Mélisande*, but are carried, perhaps, to their farthest intensity in *Aglavaine et Sélyslette*, which seems to be written for a phantom stage and to be acted by disembodied spirits. In spite of the violence of his early admirers, and of the fact that the form of his dramas easily lent itself to the cheap ridicule of parodists, the talent of Maeterlinck has hitherto met with opposition from the criticism of his time. It has been universally felt that his spirit is grave and disinterested attachment to the highest moral beauty, and his seriousness, his serenity and his extreme originality have impressed even those who are bewildered by his diaphanous graces and offended at his nebulous mysticism. While the crude enthusiasm which was felt toward Shakespeare has been shown to be ridiculous, the best judges combine with Camille Maucral when he says: "Maurice Maeterlinck est un homme de génie authentique, un très grand phénomène de puissance mentale à la fin du xix° siècle." In spite of the shadowy action of Maeterlinck's plays, which indeed require some special conditions and contrivances for their performance, they are frequently produced with remarkable success before audiences who cannot be suspected of mysticism, in most of the countries of Europe. In his philosophical writings Maeterlinck shows himself a disciple of Novalis, of Emerson, of Hello, of the Flemish Catholic mystics, and he evolves from the teachings of those thinkers a system of aesthetics applicable to the theatre as he conceives it.

(E. G.)

**MAFEKING,** a town in the British Bechuanaal division of the Cape, 870 m. N.E. of Cape Town and 492 m. S.S.W. of Bulawayo by rail, and 162 m. in a direct line W. by N. of Johannesburg. (Pop. 1904), 2713. It is built on the open veld, at an elevation of 4194 ft., by the banks of the Upper Molopo, is 9 m. W. of the western frontier of the Transvaal and 15 m. S. of the southern boundary of the Bechuanaal protectorate. The Madibi goldfields are some 10 m. south of the town. Mafeiking is thus an important trading and distributing centre for Bechuanaal and the western Transvaal. Here are, too, the chief railway workshops between Kimberley and Bulawayo. The headquarters of the administration for the Bechuanaal protectorate are in the town. The chief buildings are the town-hall, Anglican church, Masonic temple, and hospital.

Mafeiking was originally the headquarters of the Barolong tribe of Bechuana and is still their largest station, the native location (pop. 3860) being a mile distant from the town. It was from Pitsani Potlhalo (or Potlogo), 24 m. north of Mafeiking, that Dr. Jameson started, on the 29th of December 1895, on his raid into the Transvaal. On the outbreak of the Anglo-Boer war in 1899 Mafeiking was invested by a Boer force. Colonel R. S. S. Baden-Powell was in command of the defence, which was stubbornly maintained for 217 days (Oct. 12 to May 17), when a relief column arrived and the Boers dispersed (see TRANSVAAL: HISTORY). The fate of the town had excited the liveliest sympathy in England, and the exuberant rejoicings in London on the news of its relief led to the coinage of the word *mafficking* to describe the behaviour of crowds on occasions of extravagant demonstrations of a national kind. In September 1904 Lord Roberts unveiled at Mafeiking an obelisk bearing the names of those who fell in defence of the town.

R. S. S. Baden-Powell's *Sketches in Mafeiking and East Africa* (1909) and Lady Sarah Wilson's *South African Memories* (1909) deal briefly with the siege of Mafeiking.

**MAFFEI, FRANCESCO SCIPIONE,** MARCHESI DI (1675–1753), Italian archaeologist and man of letters, was born at Verona on the 1st of June 1675. He studied for five years in Parma, at the Jesuit College, and afterwards from 1698 at Rome; and in 1703–1704 he took part as a volunteer in the war of succession, fighting on the Bavarian side at Donauwerth. In 1709 he began at Padua along with Apostolo Zeno and Valisieri the Giornale dei letterati d'Italia, a literary periodical which had but a short career; and subsequently an acquaintance with the actor Riccoboni led him to exert himself for the improvement of dramatic art in Italy. His *Merope*, a tragedy, appeared in 1713; *Teatro italiano*, a small collection of works for presentation on the stage, in 1723–1725; and *Le Cerimonie*, an original comedy, in 1728. From 1718 he became specially interested in the archaeology of his native town, and his investigations resulted in the valuable *Verona Illustrata* (1731–1732). Maffei afterwards devoted four years to travel in France, England, Holland and Germany. He died at Verona on the 11th of February 1755.

A complete edition of his works appeared at Venice (28 vols., 8vo) in 1790.

**MAFIA** (Maffeta), a secret society of Sicily. Its organization and purposes much resemble those of the Camorra (q.v.). Various derivatives are found for the name. Some hold it to be a Tuscan synonym for miseria; others, a corruption of *Fr. mauvais*
(bad). Others connect it with the name of an alleged Arab tribe, Māḥīr, once settled at Palermo. Giuseppe Pitirē asserts that the word is peculiar to western Sicily and that, with its derivatives, it was then and is known to the churches, beauty or excellence. Thus, a handsome man was homely dressed, was called mafija, or mafușa. Often in Palermo the street merchants call arance-mafuse (fine oranges). Thus, Pitirē argues, mafia, applied to a man to express manly carriage and bravery, would naturally become the title of a society of the members of which were all "bravos." A less credible explanation of the term is connected with Mazzini, who is said to have formed a secret society the members of which were called Mafus, from mafia, a word composed of the initial letters of five Italian words, Mazzamizieri, and the consequence of which was the establishment in Sicily of a vast band of smugglers called Mazzini: Mafus, Mafusa, and the establishment of the Mafia. The Maffia, which survives today, was formed in 1831, when the consequence of a vow made during a dangerous illness to build a convent for the poorest friaries of the kingdom—proved to be a small Franciscan settlement here. The architects, Johann Friedrich Ludwig of Regensburg, and his son Johann Peter, took the Escorial for their model; but the imitation is less successful than the original, though the cost exceeded $4,000,000. The building is in the form of a parallelogram, measuring upwards of 800 ft. from north to south and 700 ft. from east to west; it is said to contain 866 rooms, and to be lighted by no fewer than 5,000 windows. The centre is occupied by the church, sumptuously built of marble, and richly adorned with statues and other objects of art. In each of the twin towers there is a chime of 57 bells. Part of the palace, originally designed as barracks, is used as a military academy. Joining the palace are fine gardens and a royal model farm.

MAFRA, a town of Portugal, in the district of Lisbon (formerly in the province of Estremadura), near the Atlantic coast and the right bank of the river Lizaão, and 20 m. N.W. of Lisbon. Pop. (1900), 4769. Mafra is remarkable for its monastery, church, and palace, built by John V. in 1717-1732, in consequence of a vow made during a dangerous illness to build a convent for the poorest friaries of the kingdom—which proved to be a small Franciscan settlement here. The architects, Johann Friedrich Ludwig of Regensburg, and his son Johann Peter, took theEscorial for their model; but the imitation is less successful than the original, though the cost exceeded $4,000,000. The building is in the form of a parallelogram, measuring upwards of 800 ft. from north to south and 700 ft. from east to west; it is said to contain 866 rooms, and to be lighted by no fewer than 5,000 windows. The centre is occupied by the church, sumptuously built of marble, and richly adorned with statues and other objects of art. In each of the twin towers there is a chime of 57 bells. Part of the palace, originally designed as barracks, is used as a military academy. Joining the palace are fine gardens and a royal model farm.

MAGAZINE, primarily a warehouse for goods or merchandise (Arab. makhzan, a storehouse, from khasana, to store up). In Morocco makhzan (or mahkzen) has come to be used as the name of the government. The Spaniards adopted the Arabic in the form magacen, and the English form comes through the older French magasin, modern magasin. The meaning of a storehouse or large shop, common in French, is rare in English except in the military use of the term for a building for the storage of explosives and ammunition. It is applied to the chamber of a repeating rifle or machine-gun containing the supply of cartridges. The name as applied to a periodical publication

See W. Agnew Paton, picturesquely Sicily (1898); C. W. Heckethorn, Secret Societies of all Ages (1897); Alongi, La Mafia (Turin, 1887); Le Paure, La Mafia (Paris, 1892).
containing articles on various subjects was first used in the *Gentleman's Magazine* (1731), described as "a monthly collection, to treasure up as in a magazine" articles on the subjects with which it was proposed to deal.

**MAGDALA** (more correctly **MAKDALA**), a natural stronghold in the country of the Wolo Gallas, Abyssinia, about 250 m. W. of Jibuti on the Gulf of Aden, in 11° 22' N., 39° 25' E. The basaltic plateau of which it consists rises 910 ft. above the sea. It is about three-quarters of a mile in length by less than half a mile in breadth, and lies more than a thousand feet higher than the neighbouring plain of Arogié. Chosen about 1860 by the emperor Theodore of Abyssinia as his principal stronghold in the south, Magdala owes its celebrity to the fact that, as the place of imprisonment of the English captives, it became the goal of the great English Expedition of 1868. At the time of its capture it contained huts for a population of about three thousand. The whole rock was burned bare by order of the commander of the British force, Sir Robert Napier, who, on being raised to the peerage for his services on this occasion, took the title of Lord Napier of Magdala. The plateau was subsequently refortified by the Abyssinians.

**MAGDEBURG**, a city of Germany, capital of the Prussian province of Saxony, a fortress of the first rank and one of the principal commercial towns of the German Empire. It lies in a broad and fertile plain, mainly on the left bank of the Elbe, 88 m. S.W. from Berlin and at the junction of main lines to Leipzig, Brunswick, Cassel and Hamburg. Pop. (1885), 159,520; (1900), 202,234; (1905), 240,661. It consists of the town proper, and of the five suburbs of Friedrichstadt, Wilhelmsstadt, Neustadt, Sudenburg and Buckau; the last four are separated from the town by the ramparts and glacis, but are all included within the new line of advanced bastions, while Friedrichstadt lies on the right bank of the river. In the Elbe, between the old town and the Friedrichstadt, lies an island whereon stands the citadel; this is united with both banks by bridges. With the exception of the Breite Weg, a handsome thoroughfare running from north to south, the streets of the town proper are narrow and crooked. Along the Elbe, however, extend fine promenades, the Fürstenwall and the Fürsten Ufer. To the south of the inner town is the Friedrich Wilhelms Garten, a beautiful park laid out on the site of the celebrated convent of Berge, which was founded in 686 and suppressed in 1809. By far the most important building in Magdeburg is the cathedral, dedicated to SS Maurice and Catherine, a handsome and massive structure of the 14th century, exhibiting an interesting blending of Romanesque and Gothic architecture. The two fine western towers were completed about 1520. The interior contains the tombs of the emperor Otto the Great and his wife Edith, an English princess, and the fine monument of Archbishop Ernest (d. 1513), executed in 1495 by Peter Vischer of Nuremberg. The Liebfrauenkirche, the oldest church in Magdeburg, is an interesting Romanesque edifice of the 10th and 11th centuries, restored 1860–1880.

The several other buildings are the town-hall (Rathaus), built in 1661 and enlarged in 1866, the government offices, the palace of justice, the central railway station and the exchange. The Breite Weg and the old market contain numerous fine gable-ended private houses in the style of the Renaissance. In front of the town-hall stands an equestrian statue of Otto the Great, erected about 1220. The modern streets are spacious, and the houses well-built though monotonous. There are two theatres, an agricultural college, an art school, several gymnasia, a commercial and other schools, an observatory, and two fine hospitals. The first place amongst the industries is taken by the ironworks (one being a branch of the Krupp firm, the Grusonwerke, employing about 4000 hands), which produce naval armour and munitions of war. Of almost equal importance are the sugar refineries and chisery factories. Then come establishments for making tobacco, gloves, chocolate, artificial manure, cement, varnish, chemicals and pottery. There are also distilleries and breweries, and factories for the manufacture of cotton and silk goods. Magdeburg is the central market in Germany for sugar and chicory, hay trades extensively, also in cereals, fruit, vegetables, groceries, cattle, horses, wool, cloth, yarn, leather, coal and books. A new winter harbour, made at a cost of £400,000, facilitates the river traffic along the Elbe. Three million tons of merchandise pass Magdeburg, going upstream, and nearly 1 million tons, going downstream, annually. Magdeburg is the headquarters of the IV. corps of the German army and the seat of the provincial court of appeal and administrative offices, and of a Lutheran consistory.

**History.**—Magdeburg, which was in existence as a small trading settlement at the beginning of the 9th century, owes its early prosperity chiefly to the emperor Otto the Great, who established a convent here about 937. In 984 it became the seat of an archbishop, who exercised sway over an extensive territory. Although it was burnt down in 1188, Magdeburg became a flourishing commercial town during the 13th century, and was soon an important member of the Hanse League. Its bench of jurats (Schöpensstuhl) became celebrated, and "Magdeburg law" (Magdeburger Recht), securing the administrative independence of municipalities, was adopted in many parts of Germany, Poland and Bohemia. During the middle ages the citizens were almost constantly at variance with the archbishops, and by the end of the 16th century had become nearly independent of them. It should, however, be noted that Magdeburg never became a free city of the Empire. The town embraced the Reformation in 1524, and was thenceforward governed by Protestant titular archbishops (see Bishop). On the refusal of the citizens to accept the "Interim," issued by the emperor Charles V., Magdeburg was besieged by Maurice of Saxony in 1550, and capitulated on favourable terms in November 1551. During the Thirty Years' War it was twice besieged, and suffered terribly. It successfully resisted Wallenstein for seven months in 1629, but was stormed and sacked by Tilly in May 1631. The whole town, with the exception of the cathedral, and about 140 houses, was burned to the ground, and the greater part of its 36,000 inhabitants were butchered without regard to age or sex, but it recovered from this deadly blow with wonderful rapidity. By the peace of Westphalia (1648) the archbishopric was converted into a secular duchy, to fall to Brandenburg on the death of the last administrator, which happened in 1689. In 1806 Magdeburg was taken by the French and annexed to the kingdom of Westphalia, but it was restored to Prussia in 1814, on the downfall of Napoleon. Otto von Guericke (1620–1680), ‘the inventor of the air-pump, was burgomaster of Magdeburg. Count Lazare Carnot died here in exile, and was buried in the cemetery, but his remains were exhumed in 1889 and conveyed to Paris. Luther was at school here, and sang in the streets for bread with other poor choristers.

The **ARCHBISHOPRIC OF MAGDEBURG** was carved out of the bishopric of Halberstadt when it was founded in 968, and its history is largely bound up with that of the city and of the prelates who have ruled the see. The first archbishop was Adalbert, and he and his successors had six or seven suffragan bishops. Several of the archbishops took very prominent parts in German politics. Early in the 15th century their residence was fixed at Halle, and about the same time it became the custom to select them from one of the reigning families of Germany, most often from the house of Brandenburg. The doctrines of the reformers made their appearance in the diocese early in the 16th century, and soon Archbishop Sigismund, a son of Joachim II., elector of Brandenburg, openly avowed his adherence to Lutheranism. After the issue of the edict of
restitution by the emperor Ferdinand II. in 1629, there were three rival candidates for the see, and their struggles added to the confusion caused by the Thirty Years' War. By the peace of Prague, however, in 1625, the archbishopric was given to Augustus, prince of Saxe-Weissenfels, who retained it until his death in 1680. In 1773 the area of the see was over 2000 sq. m. It included 29 towns and over 400 villages and contained about 250,000 inhabitants.

See the Regesta archiepiscopatus magdeburgensis, edited by G. A. von Müllersdorff (Magdeburg, 1876-1899); and K. Uhler, Geschichte des Erzbistums Magdeburg unter den Kaisern aus südsechsischem Haus (Magdeburg, 1887).

Distinct both from the archbishopric and from the city was the Burgraviate of Magdeburg. The office of burgrave dates from the time of Charlemagne, although its holder was not at first called by this name, and it soon became one of great importance. The burgrave was the king's representative; he was charged with the administration of the royal estates in a given district, and in general with watching the royal interests therein. The burgrave of Magdeburg was held by several counts families in turn until 1269, when it was purchased by Archbishop Conrad II., who, however, soon sold it. In 1294 it was again united with the archbishopric and the prelates retained it until 1358; then in 1579 Augustus, elector of Saxony, made an arrangement which again gave the office to the archbishops, who held it until the secularization of the see.

The Magdeburg Centuries (Magdeburger Zenturien) is the name given to the first general history of the Christian Church written from a Protestant point of view. It was compiled in Magdeburg, and the history is divided into periods of one hundred years each. It was written in Latin in 1562, its principal author being the reformer Matthias Flacius, who was assisted by other Lutheran theologians. The cost of the undertaking was borne by some of the German Protestant princes. As the Historia ecclesiae Christi it was first published at Basel in seven volumes (1559-1574). It deals with the history of the Church down to 1400, and considering the time at which it was written it is a remarkable monument to the scholarship of its authors. The earlier part of it has been translated into German (Jena, 1569-1562).

See E. Schaumbuell, Beitrag zur Entstehungsgeschichte der Magdeburger Zenturien (Ludwigslust, 1898).

MAGEE, WILLIAM (1766-1831), archbishop of Dublin, was born at Enniskillen, Co. Fermanagh, and educated at Trinity College, Dublin, where he was elected fellow in 1788. He was ordained in 1790. Two sermons, preached in the college chapel in 1798 and 1799, form the basis of his Discourses on the Scriptural Doctrines of Atonement and Sacrifice (1801), a polemic against Unitarian theology which was answered by Lant Carpenter. Magee was appointed professor of mathematics and senior fellow of Trinity in 1800, but in 1812 he resigned, and undertook the charge of the livings of Cappagh, Co. Tyrone, and Killeeleagh, Co. Down. Next year he became dean of Cork. He was well known as a preacher and promoter of the Irish reformation, and in 1819 he was consecrated bishop of Raphoe. In 1822 the archbishop of Dublin was translated to Armagh, and Magee succeeded him at Dublin. Though in most respects a timid man, he was strongly opposed to the movement for Catholic Emancipation. He died on the 18th of August, 1841.

A memoir of his life is included with the Works of the Most Reverend William Magee, D.D. (1842), by A. H. Kenney.

MAGEE, WILLIAM CONNOR (1821-1891), Anglican divine, archbishop of York, was born in Cork in 1821. His father was curate of the parish attached to the Protestant cathedral in that city; his grandfather was archbishop of Dublin. Young Magee entered Trinity College, Dublin, with a scholarship at thirteen. He was ordained to the curacy of St Thomas's, Dublin, but, being threatened with consumption, went after two years to Malaga. On his return he took a curacy at Bath, and was speedily appointed to the Octagon Chapel, where his fame both as preacher and platform speaker continued to spread. Some years afterwards he was made prebendary of Wells Cathedral. In 1866 the delicate state of his health caused him to accept the living of Enniskillen. In 1864 he was made dean of Cork and chaplain to the lord lieutenant. Here he manifested those great gifts which ultimately raised him to high office; a powerful grasp of material, moral and political problems, combined with eloquence of a high order, and illuminated with brilliant flashes of wit. In 1868 the question of the disestablishment of the Irish Church came to the front, and Magee threw himself into the task of its defence with his usual energy and vivacity. The success of his orations caused Disraeli to offer him the bishopric of Peterborough. He justified his appointment by his magnificent speech when the Disestablishment Bill reached the House of Lords in 1869, and then plunged into diocesan and general work in England. He preached three remarkable sermons on Christian Evidence in Norwich Cathedral in 1871. He took up the temperance question, and declared in the House of Lords that he would rather see "England free than England compulsorily sober," an utterance which the extreme advocates of total abstinence misquoted and attacked. He was also a supporter of the movement for abolishing the recitation of the Athanasian Creed in the public services of the Church of England, believing, as he said, that the "presence" of the damnable doctrine as it stands and where they stand, is a real peril to the Church and to Christianity itself," and that those clauses "are of no essential part" of the creed. The project was laid aside in consequence of the hostility of a large body of the clergy, reinforced by the threat of Dr Pusey and Canon Liddon to abandon their offices if it were carried. Magee took a prominent part in the Ritual controversy, opposing what he conceived to be romanizing excess in ritual, as well as the endeavour of the opposite party to "put down Ritualism," as Disraeli expressed it, by the operation of the civil law. His incisive way of putting things earned for him the title of the "Militant Bishop," but, as he himself remarked in relation to this title, his efforts were ever for peace. Unfortunately for the Church, he was not elevated to the see of York until his energies were exhausted.

He died on the 5th of May 1891, after four months after his appointment. Magee's manifold activities, his capability as an administrator, his sound judgment, and his remarkable insight into the ecclesiastical problems of his time, rank him among the most distinguished of English prelates.

MAGELLAN, FERDINAND (in Sp. Fernando Magalhães, in Port. Fernão de Magalhães) (c. 1480-1521), the first circumnavigator of the globe, was born at Sabrosa in the Villa Real district of the Traz-os-Montes province of Portugal. He was a son of Pedro de Magalhães, and belonged to the fourth order of Portuguese nobility (fidalgos de cota de armas). He was brought up as one of the pages of Queen Leonor, consort of King John (João) II "the Perfect." In 1495 he entered the service of Manuel "the Fortunate," John's successor, and in 1504 enlisted as a volunteer for the Indian voyage of the first Portuguese vicerey in the East, Francisco d'Almeida. He sailed on the 25th of March 1509; was in the battle of Macta on 20th August and was sent with Nuno Vaz Pereira to Sofala to build a Portuguese fortress at that place; returned to India early in 1508; and was again wounded at the battle of Diu on the 3rd of February 1509. At Cochín (Aug. 19, 1509) he joined Diogo Lopes de Sequeira on his famous voyage intended for the Spice Islands, when the Portuguese almost fell victims to Malay treachery at Malacca. In this crisis he fought bravely and skilfully (though it is not true, as often asserted, that he discovered the Malay plot); and before the 10th of October 1510 he had been rewarded for his many services with the rank of captain. He again distinguished himself at the taking of Malacca by Albuquerque (July-Aug., 1511), and was then sent on by the vicerey with Antonio d'Abreu to explore the Spice Islands (Moluccas). Leaving Malacca at the end of December 1521, this squadron sailed along the north of Java, passed between Java and Madura, left Celebes on their left, coasted by the Gunong Api volcano, touched at Bura, and so reached Ambonaya and Banda. At the last-named they found

...
such abundance of spices that they came straight back to Malacca without visiting Ternate, as had been intended.

Magellan returned to Portugal in 1512. On the 14th of July of that year he was raised to the rank of ſidalgo escudeiro; and in 1513 he accompanied a Portuguese expedition against Azamor in Morocco. The city was taken on the 28th-29th of August 1513, but Magellan was subsequently wounded, and lamed for life, in a sortie; he was also accused of trading with the Moors. The accusation was subsequently dropped, but Magellan fell into disfavour with King Manuel, who let him understand that he would have no further employment in his country's service (after the 15th of May 1514). Magellan formally renounced his nationality, and went to offer his services to the court of Spain. He reached Seville on the 26th of October 1517, and thence went to Valladolid to see Charles V. With the help of Juan de Aranda, one of the three chief officials of the India House at Seville, and of other friends, especially Diogo Barbosa, a Portuguese like himself, naturalized as a Spaniard, who had acquired great influence in Seville, and whom his daughter he now married, he obtained the ear of Charles and of the powerful minister, Juan Rodríguez de Fonseca, bishop of Burgos, the persistent enemy of Columbus, the steady supporter of his great successor. Magellan proposed to reach the Spice Islands of the East Indies by the west; for that purpose he hoped to discover a strait at the extreme south of South America, and is said to have declared himself ready to sail southwards to 75° to realize his project. Ruy Faleiro the astronomer, another Portuguese exile, aided him in the working out of his plan, and he found an invaluable financial ally in Christopher de Haro, a member of a great Antwerp firm, who owed a grudge to the king of Portugal. On the 22nd of March 1518, Magellan and Faleiro, as joint captains-general, signed an agreement with Charles V., by which one-twentieth of the clear profits were to fall to them; further, the government of any lands discovered was vested in them and their heirs, with the title of adelantados. On the 10th of August 1519, the fleet of five vessels, under Magellan's command, left Seville and dropped down the Guadalquivir to St. Lucar de Barrameda, at the mouth of the river, where they remained more than five weeks. On the 20th of September the armada put to sea. Of the vessels which composed it, the “Trinidad” was the flagship, and the “Vittoria” the only one which accomplished the circumnavigation. The crew, officers, volunteers, & c., numbered about 270-280, of whom the names of 268 are preserved; 237 of these received pay; at least 37 were Portuguese, 30 or more Italians (mostly Genoese), 19 French, 1 English, 1 German. Only 31 returned in the “Vittoria”; 4 survivors of the crew of the “Trinidad” reappeared later. Antonio Pigafetta of Vicenza, an Italian gentleman who has left the best history of the voyage, went as a volunteer in Magellan's suite. Faleiro stayed behind, having cast his horoscope and found that the venture would be fatal to him. The fleet was well armed, and the total cost of equipment was 8,571,000 maravedis, or 4,053 (50,000 in present terms). The fleet was later defrayed by the Spanish Crown, one-quarter by Christopher Haro and his friends. Before starting, Magellan made his will and addressed a memorandum to Charles V., assigning geographical positions connected with the controversy he was intending to settle: viz., the proper drawing of a demarcation-line between the spheres of Spain and Portugal in the East Indies, and the inclusion of the Moluccas within the Spanish sphere.

Steering south-west and calling at Tenerife (Sept. 26-Oct. 3), Magellan sighted South America at Cape St Augustine, near Pernambuco on the 29th of November; thence he followed the east coast of the New World down to the La Plata estuary, which he examined in the hope of finding a passage at this point (Jan. 11-Feb. 6, 1520). On the 31st of March following, he arrived at Port St Julian (in 29° 20' S.) where he wintered. Here he crushed a formidable mutiny (April 1-2), and made acquaintance with the natives, whom he called Patagonians (“Big Feet”), whose great size and lofty stature are magnified by Pigafetta to gigantic proportions.

Leaving Port St Julian on the 24th of August 1520, he discovered on the 21st of October the cape of the Eleven Thousand Virgins, the eastern entrance of the long-sought passage. Through this strait, 180 m. long, often narrow and very tortuous, fringed by snow-clad mountains, he guided his armada for thirty-eight days, weakened by the desertion of one vessel (the “S. Antonio”). On the 21st of November a council of pilots and captains was held to consider the continuation of the voyage, and on the 28th of November the fleet rounded Cabo Deseado, the “desired” western terminus of the strait, variously called by the first discoverers, “Victoria Strait,” “Strait of the Patagonians,” “of all Saints,” “of the Eleven Thousand Virgins,” or “of Magellan,” now only known by the last of these names. To the south of the passage lay the forbidding land “stark with eternal cold,” which from the many fires here observed Magellan named “Tierra del Fuego.” The expedition now entered the “Great South Sea,” first sighted by Vasco Nuñez de Balboa (q.v.), which, from the gentle and steady winds that drove the fleet across the immeasurable expanse, was by Magellan called “Pacific.” For ninety-eight days Magellan crossed this sea, almost beyond the grasp of man’s mind for vastness (as Maximilian of Transylvania puts it), from Cabo Deseado to the Ladrones. On the whole transit he discovered only two islands, sterile and uninhabited, which he called “St Paul’s” (Jan. 24, 1521) and “Shark Island” (Feb. 3). The first of these has been identified with Puka Puka in the Tuamotu Archipelago, the second with Flint Island in the Manihiki group; neither identification seems convincing. For most of these ninety-eight days the explorers had no fresh provisions, little water (and that bad), and putrid biscuit; the ravages of scurvy became terrible. The worst anticipations of Magellan (“he would push on, if they had to eat the leather of the rigging”) were realized; ox-hides, sawdust, and rats became coveted food. At last, on the 6th of March 1521, the Ladrones (so named by Magellan from the thievish habits of the natives) came in sight, Guam (then being probably the first port of call). Here the fleet rested, watered, revictualled and refitted; on the 9th of March they started again westward; and on the 16th of March sighted the southern point of Samar Island in the archipelago, since 1542 called the Philippines, but named by Magellan, its first discoverer, after St Lazarus. On the 7th of April the squadron arrived at Cebu, south-west of Samar, in the heart of the Philippines; here Magellan contracted a close friendship and alliance with the treacherous native sovereign, who professed Christianity the better to please and utilize his Catholic friends. Undertaking an expedition to conquer, for the Catholic faith and the king of Cebu, the neighbouring island of Mactan, Magellan was killed there in a fight with the islanders (April 27, 1521). The king of Cebu after this got into his power several of the leading personages of the squadron, including Juan Serrano, one of the two admirals elected to replace Magellan, and murdered them. The survivors, burning one of the three remaining vessels, set fire to the Philippines, and went to the Moluccas (Nov. 6), visiting Borneo on the way (July 9-Oct. 27, 1521). At Tidor a heavy cargo of cloves was taken in; the “Trinidad,” becoming leaky, stayed behind with her crew; and the “Vittoria,” under Juan Sebastian del Cano, proceeded to Europe alone (Dec. 21, 1521). To double the Cape of Good Hope the “Vittoria” reached between 40° and 41° S. (April 7-16, 1522) and suffered from contrary winds, heavy seas, scurvy and starvation. In the Cape Verde Islands (July 9-15, 1522) thirteen of the crew were detained prisoners by the Portuguese. Only thirty-one men returned with del Cano to Seville in the first vessel that had ever made the tour of the world. Though Magellan had not quite reached the Spice Islands when he fell at Mactan, his task had then been accomplished. He had already reached and passed the longitude of the Moluccas, where he had already been; the home way from the Philippines by the Indian Ocean and the Cape of Good Hope was perfectly known to the Portuguese, himself included. Magellan's name has never received its due recognition in
general history. It ranks with those of Columbus, Marco Polo, and Henry the Navigator. The circumnavigation of the globe is as great an event as the discovery of America. Magellan achieved what Columbus planned—the linking of west Europe with east Asia by direct transit over the western ocean. Had America not intervened, the project of 1492 must have failed; by 1510 European pioneers had formed a more adequate notion of the task and its magnitude.

Magellan's Straits, the Magellanic clouds (not first observed by him), and Magellan's Land—a name long given to Patagonia and that hypothetical southern continent of which Tierra del Fuego was considered only a portion, and now again bestowed by Chile on her territory in the extreme south—preserve the memory of the first circumnavigator. The largest of the oceans has also kept the flattering name given to it by the man who first crossed it.

No record of his exploits was left by Magellan himself, and contemporary accounts are less detailed and consistent than sufficient could be wished. The best is that of Antonio Pigafetta, a volunteer in the fleet. It is printed in Raimuso, and exists in four early MS. copies, one in Italian and three in French. The latter was perhaps the original of this work, which was later translated, as the knight of Rhodes, to the Frenchmen Villiers de l'Isle Adam, grand master of the order of the Hospital of St John. But this view is rejected by J. A. Robertson (see below), who believes the Arab original was translated into Latin. At the beginning of the 17th century, the Catalogue of the Library of the Indies (published by the French Crown in 1689) gives an outline of the voyage, deformed by the uncertainty of the Italian language in the hands of the Napoleon and his contemporaries of the 19th century. The first French MS. (one of the three French MSS. of which the British Academy possesses a copy), was published by the Academy of Paris in 1826. It was translated into French by Amoretti, and issued in a French MS. in 1826. The first printed edition was published in Paris in 1827. Another edition was published in London in 1829.

There are also several later editions of the work, which were of little use to the book in Venice. Of these, the first printed edition, apparently a summary of the Italian MS., was issued in French by Simon de Colines of Paris about 1585. The English edition of 1584 (or 1585). Other authorities are: (1) the narrative of an unknown Portuguese official; (2) the Deiutor or Logbook of the Seville Archives; (3) the work of Francisco Albo, contra maestre of Magellan's flagship, the Trinidad; (4) the narrative of the Portuguese, which is called Cois and Coix, written in excellent Portuguese, and printed in vol. iv of the Coleccion de noticias de la Academia de Sevilla; (5) the narrative of a Portuguese, and (6) the references in Correa and Herrera, often based on good information, and adding points of interest to other records. Of these (1) &c., and (6) are translated in the Hakluyt Society's works. These documents of the two ships (i) executed at Belem on the 17th of December 1504, on the eve of his departure with Almeida, (ii) executed at Seville on the 24th of August, 1510, just before setting out on his voyage round the world, are both of some value for his life.

The Magellanic Clouds (named after Ferdinand Magellan), two cloud-like condensations of stars in the southern constellation of Vela, about 66° S. Dec. and 5° W. Long., were discovered by R. A. The name was suggested by the resemblance of their stars as regards spectra and physical constitution to the stars of the Milky Way, though entirely detached from that object.

MAGENTA, a town of Lombardy, Italy, in the province of Milan, 16 m. by rail W. of Milan city, 69 ft. above sea-level.

situated in the midst of rich fields. Pop. (1901), 8,012. It manufactures silks and matches, and is famous for the battle (1569) in which the allied French and Piedmontese defeated the Austrians (see Italian Wars). A memorial chapel and a monument were erected on the battlefield in 1862. A crimson-purple aniline dye, discovered about the time of the battle, was given from it the name of "magenta."

MAGGIORE, LAGO (Lacus Verbanus of the Romans; Fr. Lac Majeur; Ger. Langense), the most extensive of the lakes that extend along the foot of the Alps in Lombardy, N. Italy. Its area is about 83 sq. m., its length 37 m., its greatest width 57 m., and its greatest depth 1108 ft., while its surface is 646 ft. about sea-level. It is mainly formed by the Ticino (Tessin) River, flowing in at the north and out at the south end, on its way to join the Po, but on the west the lake receives a very important tributary, the Toce or Tosa River, which flows down through the Val d'Ossola from the mountains around the Simplon Pass. Other important affluents are the Maggia (N.W.) and the Tresa (E.). The upper end of the lake (about 16 sq. m.) is in the Swiss canton of Ticino (Tessin). Locarno, at the northern or Swiss end, is 14 m. by rail S.W. of Bellinzona on the St. Gotthard line. There is a railway along the southeastern shore, from Magadino (105 m. S.W. of Bellinzona) to Sesto Calende (36 m.), at the southern end of the lake and 20 m. by rail from Novara. The east shore of the lake is reached at Luino by a steam tramway from Ponte Tresa on the lake of Lugano (8 m.), while the direct Simplon line runs along the west shore of the lake for 156 m. from near Pallanza past Baveno and Stresa to Arona, which is 23 m. by rail from Novara. On the east shore are Luino (Ital. Luvino) and Laveno. On the west shore are (reckoning from N. to S.) Cannobio, Pallanza, Baveno, Stresa and Arona. Opposite (S.E.) Baveno are the famous Borromeo Islands, on the largest of which (Isola Bella) are very remarkable gardens (formed about 1667), wherein many tropical plants are cultivated, which, while south-west of Baveno rises the glorious view-point of the Monti Mottarone (4825 ft.) beyond Lago Maggiore and the northern end of the Lake of Orta.

In the morning the tramontana wind blows from the north shore of the lake, while in the afternoon the inversa, blowing from the south, prevails. The first place was planted on the lake in 1826.

(W. A. B. C.)

MAGIC (i. e. "art magic"; Lat. artis magica), the general term for the practice and power of wonder-working, as depending on the employment of supposed supernatural agencies. Etymologically the Gr. μαγεία meant the science and religion of the magi, or priests of Zoroaster, as known among the Greeks; in this sense it was opposed to γοητεία ( necromancy) and φαρμακεία (the use of drugs); but this distinction was not universally recognized, and γοητεία is often used as a synonym of μαγεία. There is no general agreement as to the proper definition of "magic," which depends on the view taken of "religion."

I.—Nature of Magic

Theories of Magic.—Existing theories of magic may be classified as objective or subjective. The objective school regards magic as a thing by itself, entirely distinct from religion, recognizable by certain characteristics, and traceable to a definite psychological origin. Magic, in this view, is a system of savage science based on imaginary laws supposed to operate with the regularity ascribed to natural laws by the science of to-day. If practices prima facie magical form part of the recognized ritual of religion, it is because the older ideas have persisted and at most assumed a veneer of religion. For the subjective school, on the other hand, only those rites are magical which their practitioners qualify with the name of magic; there is no inherent quality which makes a rite magical; practices based on belief in the law of sympathy may be religious as well as magical; rites may pass from the category of religion to that of magic when public recognition is withdrawn from them.

1 For what is often called "magic," but is really trick-performance, see Conjuring.

MAGELLANIC CLOUDS—MAGIC
a. For E. B. Tylor the distinguishing characteristic of magic is its unreality; it is a confused mass of beliefs and practices, and their unity consists in the absence of the ordinary nexus of natural cause and effect. Under the general head of magic he distinguishes (i) a spiritual and (ii) a non-spiritual element. (i) The former is made up of the belief that certain objects or beings are capable of exercising a will over the spirits which develop in the darkness or darkness itself, and that these spirits themselves have power over the nature of the gods; hence, in Tylor's view, this form of magic is merely an inferior branch of religion. (ii) The non-spiritual part, for which the category of magic would be unnecessary, is the belief that the human mind has power over the physical world. It is not more so, in magic as in technology or any other important element in human life. The correspondence between magic and technology can be traced, for the gestures of the craftsman are as effective as the spells of the magician. The technical skill of the latter is of no account, and his gestures are not prescribed in the objects used in magical operations. The underlying idea of magic is dynamical; to this power may be ascribed the name of mana (see below), of which sanctity is a special development. This mana is then the power which is exercised by the ritual act, and distance is no obstacle to contact; wishes are immediately realised; but law reigns in the milieu in question, necessary relations are conceived as existing. The notion of time as it is found in the world of magic is even more alien from European ideas; the notion of time is largely forgotten, and in his typology of operations the magician is not interested in different stages of development, but in his concentration of attention is precisely calculated to favour illusions; it is indeed the ordinary condition of successful hypnotism; even in civilized countries collective hallucinations without verbal communication are to be observed.

b. In the examination of the magical practices, the religious concepts are to be observed. Religion is a system of beliefs which is the result of a series of actions, and which is itself the cause of further actions. The belief is that the god resides in them.

c. Hubert and Mauss have made the most complete and systematic study of magic which has yet appeared. They hold that, in taking part at a rite, a magician is ipso facto in the hands of others, and that the acts of the rite, whether performed by human beings or by the gods, are put down to the fact that a god resides in them.

d. Hubert and Mauss have made the most complete and systematic study of magic which has yet appeared. They hold that, in taking part at a rite, a magician is ipso facto in the hands of others, and that the acts of the rite, whether performed by human beings or by the gods, are put down to the fact that a god resides in them.

Definition of Magic—At a definition of magic we may either follow the a priori road mapped out by Frazer and decline to recognize the distinction actually drawn by various societies between magical and religious practices; or we may ask what magic and corresponding terms actually connote. Frazer's method ignores the fact that magic, like religion, is an institution, i.e., a product of society, not of any individual; there is no more reason to suppose that a child reared in isolation would develop any kind of magical practices than that it would invent for itself a religion; but if this is the case,
the associationist account of magic cannot be true. It is therefore by an analysis of actually existing practices that we must define and limit the term magic. There is, however, a serious difficulty in the way of determining the attitude of non-European peoples towards religio-magical practices; general terms are things of slow growth; it is therefore prima facie improbable that peoples in the lower stages of culture will have anything corresponding to our terms “religion” and “magic”; moreover, if we are right in assuming the fundamental unity of the two, it is by no means certain that they have even the consciousness of any distinction. Even when this consciousness is present, it by no means follows that the whole of the field is mapped out according to our categories; there will be a large indeterminate area which is neither magical nor religious. This suggests that the consciousness of the educated Occidental, for which the spheres of magic and religion in civilized society are sharply defined and contrasted, should be the ultimate arbiter; but here again we are confronted with a difficulty, for, to the educated man, the characteristic of magic is its unreality, and this does not help us to distinguish primitive magic and religion.

We must, it appears, determine the relation of magic to religion by an analysis of the conceptions of those who believe in both; but in so doing we must consider that, like all other institutions, magic has a history. Even if we go back to the 16th century and take the view of magic then held by the average European, it is still a complex idea. When we ask what the most primitive races now on the earth regard as magic, we are applying to their ideas a touchstone made for a very different age and culture; as well might we ask what their theory of knowledge is. If, however, we reverse the process and ask what elements of primitive institutions correspond most nearly to later conceptions of magic, we can at once say that the forbidden and private arts are the prototypes of the magic of primitive peoples. Magic is therefore the practice of maleficient arts which involve the use of religio-magical power, with perhaps a secondary idea of the use of private arts, which are to benefit, not the community as a whole, but a single individual. Religion in the lower stages of culture is essentially the tribal creed which all practise and in which all believe; if therefore an individual has a cult of his own, even if otherwise indistinguishable from a public cult, it is for this very reason on a lower plane, and probably corresponds in a degree to what is later regarded as magic. But our information as to the attitude of the uncivilized towards magico-religious rites in general is seldom sufficiently clear; our terminology is influenced by the prepossession of alien observers whose accounts cannot be assumed to correspond to the native view of the case.

Magico-religious Force.—The mere fact that we cannot draw an exact line between magic and religion suggests that they may have some fundamental feature in common. Both terms have greatly changed their connotation in the course of their existence; religio seems to have meant originally καραμελος (magical spell), and Pliny says that μαγεία is a deceptive art compounded of medicine, religion and astrology. Among the Greeks, on the other hand, μαγεία occupied a respectable position. More important is the fact that taboo (q.v.) is both religious and magical. There is a universal tendency to regard as magical the religions of alien races, as well as national religions which have been superseded; Leland tells us that witchcraft in Italy is known as la vecchia religione. An examination of the ideas of primitive peoples shows that there is a widely found notion of a power which manifests itself both in religion and magic. Observers have often been content to describe ceremonies without attempting to penetrate to the fundamental ideas which underlie them; this is particularly the case with magic, and only recently have anthropologists realized that in many primitive societies exists a fairly well-defined idea of magico-religious power, to which the generic name of mana from the Melanesian word, has been given.

a. Mana in Melanesia is a force, a being, an action, a quality, or a state; it is transmissible and contagious, and is hence associated with taboo; it may be regarded as material and seen in the form of flames or heard; it is the power which is inherent in certain spirits, among which are included such of the dead as are denominated tindaes; it may also be a force inherent in some inanimate object, such as a bird or a stone, the causes that it can perform are therefore limited and does not act mechanically; it is the power of the magician and of the rite; the magic formula is itself mana. There seem to be a variety of manas, but probably the underlying idea is essentially one, though it be in various forms. Two forms follow that it can act; the first consciousness of this unity. Hubert and Mauss go even further and regard all force as mana; it is a quality added to objects without prejudice to their other qualities, one which supplements without destroying the mechanical action of the object.

b. Similar ideas are found in other areas. (i) The continental Malays have a word Kramat (hrm), which means sacred or magical; in Indo-China the Barmans use the word dong; in Madagascar hasina seems to embody part the same notion; (ii) In Africa the idea is less apparent; perhaps the ngai of the Tangani tribe corresponds more clearly to the notion of mana; on the Congo kibis has a similar but more restricted sense. (iii) In Australia there are two, or perhaps three, kinds of magical power distinguished by the aborigines; all over the continent we find the maleficent power, boolya in West Australia, arunggullika in the central tribes, kookie in New South Wales; the central tribes have certain objects termed curtinga, to which magical power (which we may term curtinga) is attributed; the power of magicians is held to reside in certain stones, called atnonara, and in this we must, provisionally at any rate, see a third kind of magical power: curtinga is benedict and seems to originate from the primitive magic of the pre-scientific stage, and the intermediate mana, created by means of incantations or acquired by contact with certain objects; the power of the magicians seems to proceed from the ancestors in like manner. (iv) In America these ideas are often found in the form of aثنية, which has been described by J. N. B. Hewitt; everything in nature, and particularly all animate objects, have their orenda; so have gods and spirits; and natural phenomena are the product of the orenda of their spirits. Religion in the form of mana is found from the earliest times among the Inuit to the cry of the birds, the rustling of the trees, the soughing of the wind, are expressions of their orenda; the voice of the magician is orenda, so are the prayers and the spell; and in fact all rites orenda is above all the power of the maize spirits, the practice of mana, among the Sioux warakanda, mahowas, &c., among the Shoshones pokunt; all of which seem to carry, at last in part, the same signification. In Central America, according to Hubert and Mauss, natural and supernatural correspond closely; the supernatural may be found in more advanced nations; the Hindu brakman is identified by Hubert and Mauss as the correlative of mana; in Greece φειδος is possibly the echo of a similar idea; but we are yet far from having adequately fathomed the dynamical theories of pre-scientific days.

Origin of Magic.—The associationist theory of magic sets out with the assumption that primitive man began with general conceptions; he started with certain means at his disposal—the law of sympathy—which he could, in his own belief, influence the other world. But it is more probable that he argued from concrete instances and derived little by little abstract ideas of magical power.

da. Death and disease are universally regarded by uncivilized peoples as due to so-called “magic,” i.e., to non-natural causes. Primitive man was familiar with the wounds and bruises caused by physical means; he would naturally attribute any pain not so caused to the operation of analogous but invisible weapons, and eventually attempt to discover how he himself could apply on his own behalf the forces thus used against him. Similarly he may have asked himself what causes were to be attributed the superiority of one man over another; he may have decided the problem by referring it to some secret power and may have found that way in which this power could in individual instances be increased. In fact we may say generally that man probably explained the already existing and happening by reference to the supernatural, and then endeavoured to control the supernatural to control the future.

db. Ritual, however, (the primitive magico-religious plasm), is negative as well as positive. The corpse is uncanny, and man’s dread of the corpse may well have been an early development; this is true of the horror, too, which the uncanny produces. The superstition crystallized into taboo, the magico-religious prohibition. The notion of the uncanny, once arrived at, may have been exploited positively; psychical abnormalities are present among savage races in very remarkable forms, and may have played an important part in the stage in human history they doubtless suggested the possibility that man might exploit them for the collective advantage. But it by no means follows that beneficent rites were originally regarded as magical; and finally, there is no evidence that mana is a very odious of the tribe or nation. The limits of magic or its corollaries in the lower stages of culture are thus far undecided.

c. Magic as it represents itself to the Occidental mind of the present day, and perhaps to the great part of the inhabitants of the world.
seems to be a thing of gradual growth. (i) In the earlier stages there was probably no animistic feature about magic; it was essentially the "prohibited." (ii) Then with the rise of animistic beliefs and practices came the association of the magician with demons—the spirits of animals, plants, and inanimate objects. Hence, the co-operation of the powers of the magician are often now held to depend on these substances, which not in the position of gods; such recognition, worship, or cult as they received was often not a social institution, but the work of individuals, liable to fall into desuetude at the death of the individual, if not earlier. (iii) Again, the magical tends to be the less important and eventually the less respectable; therefore ancient cults which are conquered, like the religion of Rome by Christianity, cannot be traced as within the sphere of magic and witchcraft. (iv) All non-animistic practices tend to become sopis facto magical; many ritual prohibitions fall under the head of negative magic. Religion is predominantly animistic, and with the removal of religion, magical and religious, become confused, as objects, not sources, of magical influence. Magic is sometimes made to depend upon the activity of demons and spirits, and it is true that the magician usually if not invariably has a spirit helper, often an animal; but there is no evidence that magical power had ever been confined to those who are thus aided. It is not easy to define the relation of fetishism (q.v.) to magic.

**Magic and Demonology.**—Primitive psychology tends to anthropomorphize and personify; it is in many of its stages inclined to an animistic philosophy. To this do. It is the difficulty of distinguishing magic from religion. In many rites there is no obvious indication that a spirit or personal being is concerned. A portion of the ceremonies in which the spirits of the dead are concerned falls under the head of religion (see Ancestor Worship), but in the very name "neromancy" (σέχος, corpse) lies an implication of magic; and dealings with the departed are viewed in this light in many parts of the world, sometimes concurrently with a cult of ancestors. Side by side with the human souls we find demons (see Demonology), but on the whole only a small proportion of the world of spirits is regarded as powerful. In more primitive cases, the spirits, in addition, are objects, not sources, of magical influence. Magic is sometimes made to depend upon the activity of demons and spirits, and it is true that the magician usually if not invariably has a spirit helper, often an animal; but there is no evidence that magical power had ever been confined to those who are thus aided. It is not easy to define the relation of fetishism (q.v.) to magic.

**Magic and Science.**—It is a commonplace that the sciences have developed from non-scientific beginnings; the root of astronomy is to be sought in astrology (q.v.), of chemistry in alchemy (q.v.), of leechcraft in the practices of the savage magician, who depends for much of his success on suggestion, conscious or unconscious, but also relies on a pharmacopia of mean extent. The dynamical theory of magic and religion brings primitive man from one point of view far nearer to the modern man of science than was previously suspected, we may fairly say that the Australians have an idea not unlike that of the transformation and conservation of energy, that this energy they store in accumulators, transmit by means of conductors, and so on. The study of these complicated ideas only serves to show how far the present-day peoples in the lower stages of culture have travelled from the primitive man who knew neither magic nor religion. But it is perhaps less in respect of abstract ideas than by its concrete investigations into properties, experiment and otherwise that magic has been the forerunner of science.

**Magic and Divination.**—Magic is an attempt to influence the course of events, divination (q.v.) to foresee them; but divination is frequently regarded as magical. It is certain that a large part of divination is religious, and the knowledge is explained as a message from the gods; but necromancy, the practice of discovering or obtaining by means of divination, is in many respects essentially magical. Perhaps the magical character of divination may be in part explained, when we regard it as a group of practices in many varieties of which animism plays no part, for non-animistic ceremonies tend to be regarded as magical (cf. rain-making). Thus, heteroscopic divination seems to involve the idea of what may be termed a return current of magico-religious force; the event is not influenced, but itself determines the issue of the diviner's experiment.

## II. Laws and Ritual of Magic

The practice of magic involves the belief in the operation of certain laws, and demands certain conditions. The number of positive rites is not unlimited; a certain rite tends to become stable and is finally used for all sorts of purposes, and each magician tends to specialize in this respect. Just as there are certain sciences of a religious or a magical kind, and the rain-maker is not the same as the fetish-man, so within the school there are various groups, differentiated not by the purposes at which they aim nor by the powers they claim to possess, but by the ceremonies in which they practice. Chief among the laws lying at the base of magical practice is that of sympathy.

**Sympathy.**—That the law of sympathy is an essential element of magic is admitted equally by the associationist school and by its critics. Under the head of sympathy are embraced the laws of contiguity or contagion, of similarity or homeopathy, and of contrariety or antipathy.

a. In its simplest form the law of contiguity asserts that whatever has once formed part of a body continues to form part of it or to represent it for magical purposes; thus, by obtaining possession of the hair of a dead person, that of a child, that of a dog, that of a horse, and by working upon them, it is held to be possible to produce on the actual human body the effects which are in reality produced on the body of the animal that is represented. This is, for example, the object of the magical rite. As is clear from the well-known case of the "life tree," the current magical power of the animal is transferred to the latter; if the life of a man is supposed to be bound up with the life of a tree, then any injury to the tree will injure the man, and it is equally believed that the death of the man will fail to be manifest by the withering of the tree, and that its withering will manifest the death of the man. This relation is predicated of wizards or witches and their animal familiars; it is then known by the name of "repercussion." It is not only upon parts of the body that contagious magic can be worked; anything may have been in contact with the body, such as clothes, and the use of which has been in part assimilated by the body, such as the remains of food, and even representations of the body or of parts of it such as footprints, etc., may be used as objects of magical rites, in order to transmit the influence of the body. This is perhaps the widest use. The contact demanded may be actual, or mediate, for in Australia it suffices to connect the magician and his patient by a thread in order that the disease may be removed. (i) The use of magical power does not work on the actual body of the patient; it works itself as the whole spread out in the world; in nearly every part of the world it is the practice to suspend wool or rag to trees associated with some spirit, or, in Christian countries, with some saint, in order to reap a benefit; similarly nails are driven into trees or images; pins are dropped into wells, stones are cast upon cairns, and missiles aimed at various holy objects; but it cannot be assumed that the same relation lies at the root of the whole group of practices. (ii) This transference of magical power can work both ways; it is held that in many parts of the world relatives, and in particular the father of a new-born child, are compelled to practise various abstinence, in order that the health of the child may not be affected, members of the patient's family and household may be protected. (iii) In this direct transference of qualities is exemplified another magical process, which may also be referred to the operation of the law of sympathy; it is a world-wide belief that the assimilation of food involves the transference to the eater of the qualities, or of some of them, inherent in the source of the food; a South African warrior, for example, may not eat hedgehog, because the animal is held to be cowardly and the eater would himself become a coward; on the other hand, the flesh of lions is fit meat for brave men, because they at the same time transfer its courage to themselves.

b. The law of homeopathy takes two forms. (i) The magician may proceed on the assumption that like produces like; he may, for example, take an image of what he wants to do; or he may manipulate objects that or otherwise under the belief that it should or otherwise influence under the belief that it represents the human being against whom his malefic is directed, and that without any contact, real or pretended; so that any results produced on the image, which may be replaced by an animal or a portion of one, are equally produced in the human being. There need not even be any resemblance between the representation and the person or thing represented; a pot may serve to represent a village; hence step by step we pass from the representation to the actualization of a representation. The idea also manifests itself in the formula similia similibus curantur; the Brahman in India treated dropsy with aublions, not in order to add, but to subtract from, the quantity of liquid in the patient's body.

Some statements of the law of sympathy suggest that it is absolute in its application. It is true that the current of magical power is sometimes held to be transmitted along lines indicated
by the law of sympathy, without the intervention of any volition, human or otherwise; thus, the crow which carries stray hairs away from the dead and enters them into the stone {_of a rite} is now supposed to be engaged in a magical process; but it is commonly held that the person whose hair is thus used will suffer from headache or other maladies; this seems to indicate that the law of sympathy operates mechanically in certain directions, though the belief may also be explained as a secondary growth. In general the operation of these laws is limited in the extreme.

For example, the medieval doctrine known as the Law of Signatures asserted that the effects of remedies were correlated to their external qualities; bear’s grease is good for baldness, because the bear is a hairy animal. But the transference was held to terminate with the acquisition by the man of this single quality; in some magical books powdered mummy is recommended as a means of prolonging life, but it is simply the age of the remedy which is to benefit the patient; the magician who removes a patient’s pains or diseases does not transfer them to himself; the child whose parents eat forbidden foods is held to be affected by their transgression, while they themselves come off unharmed.

The Magic of Names.—For primitive peoples the name is as much a part of the person as a limb; consequently the magical use of names is in some of its aspects assimilable to the processes dependent on the law of sympathy. In some cases the name must be withheld from any one who is likely to make a wrong use of it, and in some parts of the world people have secret names which are never used. Elsewhere the name must not be told by the bearer of it, but any other person may communicate it without giving an opening for the magical use of it. Not only human beings but also spirits can be coerced by the use of their names; hence the names of the dead are forbidden, lest the mention of them act as an evocation, unintentional though it be. Even among more advanced nations it has been the practice to conceal the real name of supreme gods; we may probably explain this as due to the fear that an enemy might by the use of them turn the gods away from those to whom they originally belonged.

For the same reason ancient Rome had a secret name.

Magical Rites.—The magic of names leads us up to the magic of the spoken word in general. The spell or incantation and the magical formula are the name of the person, but are carried up in a very frequently symbolic or sympathetic in nature; sometimes they are mere reversals of a religious rite; such is the marching against the sun (known as widdershins or detour); sometimes they are symbolic invocations, just as religious. (b) There are many types and necessary steps to the consecration of the names of the gods, which consist in simply reciting the effect intended to be produced, describing the manual act, or, especially in Europe, telling a mythical narrative in which Christ or the apostles figure, and in which they are represented as performing acts of which the magician is supposed to have the power, or doing things which the magician has the power of effecting. Some formulae may be termed sympathetic; it suffices to name the result to be produced in order to produce it; but often an incantation is employed, not to produce a result directly, but to coerce the will of the other to fall into harmony with his own, and as long as that will is maintained the language of the incantations often differs from that of daily life; it may be a survival of archaic forms or may be a special creation for magical purposes. In many languages the word used to express the idea of magic means an act, a deed, and it may be assumed that few if any magical ceremonies consist of formulae only; on the other hand, it is certain that no manual act in magic stands absolutely alone without oral rite; if there is no spoken formula, there is no magic. The use of signs or symbols is found throughout the world; but among the Chippewas it is necessary to discover the relative proportions and importance of manual and oral acts. Not only the words but also the tone are of importance in magic; in fact, the tone may be the more important. Rhythm and regulated speech are characteristic of magical utterances. (c) As preliminaries, more seldom and necessary in oral than in manual acts. (d) The feature of the rite, manual or oral, we usually find a certain number of accessory observances prescribed, which find their parallel in the sacrificial rite. For example, it is laid down at what time of year, at what period of the month or week, at what hour of the day a rite must be performed; the waxing or waning of the moon must be noted and certain days must be avoided altogether. Similarly, certain places may be prescribed for the performance of the ritual; often the altar of the gods serves magical purposes also; but elsewhere it is precisely the impure sites which are devoted to magical operations—the cemeteries and the cross roads. The instruments of magic are in like manner often the remains of a sacrifice, or otherwise sacred. Magic is, of course, beyond the animal or vegetable world; they must be sought at certain points, May Day, St George’s Day, Midsummer Day, &c. The magician and his client must undergo rites of preparation and the exit of spells must be made without delay.

Magicians.—Most peoples know the professional worker of magic, or what is regarded as magic. (a) In most if not all societies magic, or certain sorts of it, may be performed by any one, so far as we can see, who has mastered the necessary ritual; in other cases the magician is a specialist and is only permitted to perform certain rituals by licence of a seventh son of a seventh son; to simple inheritance (families of magicians in modern India, rain-makers in New Caledonia); to revelation from the gods or the spirits of the dead (Malays), showing itself in the phenomena of possession, or to initiation by other magicians. (b) From a psychological point of view it may probably be said that the initiation of a magician corresponds to the “development” of the modern spiritualistic medium; that is to say, that it resolves itself into exercises and rites which have for their object the creation or evolution of a secondary personality. From this point of view it is important to notice that certain things are forbidden to magicians under pain of loss of their powers; thus, hot tea is taboo to the Arunta medicine man, and, in many of the secondary personalities, it is desired to disappear, it must be remembered that to the physiological effects, if any, must be added the effects of suggestion. Of this duplication of personality various explanations are given; in Siberia the soul of the magician is said to wander into the other world, and this is indirectly spread through the belief that it is supposed to remain on earth, his soul is again believed to wander, but there is an alternative explanation which gives him two or more bodies. Here we reach a point at which the familiar makes its appearance; this may be a sacrifice, a sort of life index or animal helper (see LYCANTHROPHY); in fact, the magician’s power is sometimes held to depend on the presence—that is, the independence—of his animal auxiliary. Concurrent with this there is a belief that the animal has the power of making the magician appear after it, before the animal makes its appearance, and this makes it a double of the magician, or, from the psychological point of view of a phase of secondary personality. (c) In many parts of the world magical societies and religious cults—such as the Telephone Temple—outside of which we are rarely informed of the proceedings of the dedicated individuals, in Europe the meetings of heretics seem to be responsible for the promiscuity of the idea if not for its origin (see WITCHCRAFT).

The magician is often regarded as possessed (see POSSESSION) either by an animal or by a human or super-human spirit. The relations of these to the magician, and the common belief that the supernatural powers of the initiation of the magician is regarded as the work of the gods, the magician is for obvious reasons likely to develop into a priest, but he may at the same time remain a magician; where a religion has been supplanted, in which it was not supposed to assist the human soul in any way, especially in spiritual development, but to supercede them, one and all magicians; in the medieval church, priests were regarded as especially exposed to the assaults of demons, and were consequently often charged with working magic. The great magicians who are gods rather than men—e.g. kings of Fire and Water in Cambodia—enjoy a reverence and receive a cult which separates them from the common herd, and assimilates them to priests rather than to magicians. The function of the so-called magician is often said to be beneficent; in Africa the witch-doctor’s business is to counteract evil magic; in Australia the magician has to protect his own tribe against the assaults of hostile magicians of other tribes; and in Europe “white magic” is the correlative of this beneficent magic, but none know how far the beneficent virtue is regarded as magical outside Europe.

Talismans and Amulets. Inanimate objects as well as living beings are credited with stores of magical force; when they are regarded as bringing good, i.e. are positive in their action, they may be esteemed as having the power of neutralizing or negating evil; when they are regarded as doing harm, they are actively evil; in their action, and their function is to avert evil; a single object may serve both purposes. Broadly speaking, the fetish, whose “magical” properties are due to association with a spirit, tends to become an amulet when the spirit is banished by a magical process. The amulet originally carried as means of union between him and his manto, is perhaps the prototype of many European charms. In other cases it is some specific quality of the object or animal which is desired; the boxtail of the rabbit in India, the hair of the wolf in Europe, was a favorite amulet. This is applicable to the wearer; the Luikungans of Vancouver Island rub the ashes of wapses on the faces of their warriors, in order that they may be pugnacious. Some Bechuana wear a ferret as a charm, in the belief that it will make them difficult to kill, the animal being pugnacious and tenacious of life. Among amulets may be mentioned horns and crescents, eyes or their representations, and grotesque figures, all of which are supposed to be powerful against the Evil Eye (q.v.).
Tylor has shown that the brass objects so often seen on harness were originally amuletic in purpose, and can be traced back to Roman times. Some amulets are supposed to protect from the evil eye simply by attracting the glance from the wearer to themselves, but, as a rule, magical power is ascribed to them.

Evil Magic.—The idea of "black" magic is to inflict injury, disease, or death on an enemy, and the various methods employed illustrate the general principles dealt with above and emphasize the conclusion that magic is not simply a matter of sympathetic rites, but involves a conception of magical force. (a) It has been mentioned that the animal magnet is particularly used in the Mohave ceremony; the medicine man follows his victim till he spits on the ground; collecting the spit mingled with dust on the end of a stick, the magician puts it into a tube made of a poisonous plant together with other substances which are thrown into the water in which the victim is afterwards thrown by lightning; the whole is buried with seven yellow stones at the foot of a tree struck by lightning, and a fire is built over the spot; the magician fasts till the ceremony is over. Probably the worst done to feed on the victim's soul, which is said to become "blue" when the charm works; the yellow stones are the emblem of trouble, and lightning-struck trees are reputed powerful in magic. If the charm does not work, the victim survives the critical seven days, and the magician and his employer are themselves in danger, for a charm gone wrong returns upon the head of him who sent it forth. (b) In homeopathic magic the victim is represented by an image or other object. In the Malay Peninsula the magician makes an effigy, and by disease, or the very opposite, of the sick person cause sickness, you pierce the eye and blindness results; or you pierce the waist and the stomach gets sick. If you want to cause death, you transfuse the head with a palm twig; then you enshroud the image as you would a corpse, and you are ready to go. If the curse is over the dead; then you bury it in the middle of the path which leads to the place of the person whom you wish to charm, so that he may step over it. Sometimes the wizard repeats a form of words signifies evil, and the earth quakes, the birds fly away, and then projecting the magical influence from it. It is perhaps the most potent form of evil magic in Australia; in the Arunta tribe a man desiring of using one of these pointing sticks or bones goes away by himself into the bush, puts them on the ground and covers the image over with a cloak; then giving a few words, he is said to become a "sorcerer." After a time he brings the image back to the camp and hides it; then one evening after dark he takes it and creeps near enough to see the features of his victim; he stoops down with the image, and even then, loudly addresses the image and then projects the magical influence over it. The evil spirit, oranggulita, is said to go straight to the victim, who sickens and dies without apparent cause, unless some medicine-man can discover what is wrong and save him by his magic. (c) The medicine man is the chief actor in the ceremony, for the magician would at once be killed if it were known that he had used it. (d) Magicians are often said to be able to assume animal form or to have an animal familiar. They are said to suck the blood of a sleeping person, or eat the liver of a corpse. (e) Magician is said to steal his soul, thus causing sickness and eventually death. These beliefs bring the magician into close relation with the werwolf (see Lycanthropy).

Rain-making.—In the lower stages of culture rain-making assumes rather the appearance of a religious ceremony, and even in higher stages so much is it associated with music that it is only by the voices, or the music, of the dancers and singers that the spell is complete. The rhythm is calculated to suit the action of rain. If no rain comes they say that another tribe has stopped their power or that the Muru-muru (ancestors) are angry with them. (b) Rain-making ceremonies are far from uncommon in Europe. Sometimes the images of saints are carried to a river or a fountain and dunked or sprinkled with water in the belief that rain will follow; sometimes rain is said to descend when the waters of certain springs are troubled; perhaps the idea is that the rain-god is disturbed in his haunts. But perhaps the commonest method is to duck or drench a human figure or puppet, who represents in many instances the vegetation demon. The gipsies of Transylvania celebrate the festival of "Green George" at Easter or on St George's Day; a boy dressed up in leaves and blossoms is the principal figure; he throws grass to the cattle of the tribe, and after various ceremonies a promise is made of throwing him into the water; but in fact only a puppet is ducked in the stream.

Negative Magic.—There is also a negative side to magic, which, together with ritual prohibitions of a religious nature, is often embraced under the name of taboo (g.v.); this extension of meaning is not justified, for taboo is only concerned with sacred things, and the mark of it is that its violation causes the taboo to be transmitted. All taboos are ritual prohibitions, but all ritual prohibitions are not taboos; they include also (a) interdictions of which the sanction is the wrath of a god; these may be termed religious interdictions; (b) interdictions, the violation of which will automatically cause some undesired magico-religious effect; to these the term negative magic should be restricted, and they might conveniently be called bans; they correspond in the main to positive rites and are largely based on the same principles.

(a) Certain prohibitions, such as those imposed on totem kins, signifying a definite and immediate place; they depend on the sanctity of the totem without being taboos in the strict sense; to them no positive magical rites correspond, for the totemic prohibition is clearly religious, not magical.

An orientation of negative magic may be mentioned (1) the couvade, and prohibitions observed by parents and relations generally; this is most common in the case of young children, but a sympathetic relation is held to exist in other cases also. In Madagascar signs of prayer are found on the downy bed of the dying child, and the death of the child's father; the sympathy between father and son establishes a sympathy between the father and objects touched or eaten by the son, and, in addition, the fall of the bananas is equated and it is said that he will never die. (2) Any person who, through sorrow, is said to be so affected that his hearer may not be faithless to him when he is absent; if a man is destined to be killed or wounded. Ownership, too, may create a sympathetic relation of this kind, for it is believed in parts of Europe that if a man sells a swallow's cow will give bloody milk. In the Sudan, the future Queen of Ashanti is supposed to have caused an old man to die. She thus succeeded to the throne. In Madagascar it is said that a man might be killed or wounded. Certain magical objects are frequently used to protect from evil. (b) Some objects, such as the dog, are forbidden, just as of the lion, are prescribed; they may never be used, used only in certain cases, or used in others, even by the wizard himself be taboo. (c) The use of certain magical objects is prohibited; (d) Words may not be used; Scottish fishermen will not mention the pig at sea; the real names of certain animals, like the bear, may not be used; the names of the dead may not be mentioned; a sacred language must be used, e.g., camphor language in the Malay Peninsula, or only words of good omen (cf. Gr. ευγενέρος); or absolute silence must be preserved. Personal names are concealed; a man may not mention the names of certain relatives, &c. There are customs of avoidance not only as to (iv) the names of relatives, but as to the persons themselves; the mother-in-law must avoid the son-in-law, and vice versa; sometimes they may converse at a distance, or in low tones, sometimes not at all, and sometimes they may speak together. (e) Sometimes a man is said to be protected at random, we have prohibitions relating to numbers (cf. unlucky thirteen, which is, however, of recent date), the calendar (Friday as unlucky), May as an unlucky month for marriage, places, persons, &c. An origination of negative magic is impossible to enumerate even the main classes. The individual origin of such beliefs, which with us form the superstitions of daily life but in a savage or semi-civilized community play a large part in regulating conduct, is often shrouded in darkness; the meaning of the positive side is easily forgotten; the negative side is observed and, in general, it is not noticed as a collection of some unknown misfortune. Sometimes we can, however, guess at the meaning of our civilized notions of ill luck; it is perhaps a survival of the savage belief that stepping over a person is injurious to that person. In Madagascar, for example, the witch or assassin is said to be in a certain place, and in the one case the luck is taken away by the person stepping over, in the other left behind by the person passing under.

History of Magic.—The subject is too vast and our data are too slight to make a general sketch of magic possible. Our knowledge of Assyrian magic, for example, hardly extends beyond the rites of exorcism; the magic of Africa is most inadequately known, and only in recent years have we well-analysed
MAGIC SQUARE

repertories of magical rituals from any part of the world. For certain departments of ancient magic, however, like the Pythagorean philosophy, there is no lack of illustrative material; it depended on mystical speculations based on numbers, on sacred principles. The importance of numbers is recognized in the magic of America and other areas, but the science of the Mediterranean area, combined with the art of writing, was needed to develop such mystical ideas to their full extent. Among the neo-Platonists there was a strong tendency to magical speculation, and they sought to impress into service the demons with which they peopled the universe. Alexandria was the home of many systems of theurgic magic, and gnostic gems afford evidence of the nature of their symbols. In the middle ages the respectable branches of magic, such as astrology and alchemy, included much of the real science of the period; the rise of Christianity introduced a new element, for the Church regarded all the religions of the heathen as dealings with demons and therefore magical (see WITCHCRAFT). In our own day the occult sciences still find devotees among the educated; certain elements have acquired a new interest, in so far as they are the subject matter of psychical research (q.v.) and spiritualism (q.v.). But it is only among what are regarded as the lower classes, and in England especially the rural population, that belief in its efficiency is attached to any large extent.

Psychology of Magic.—The same causes which operated to produce a belief in witchcraft (q.v.) aided the creed of magic in general. Fortuitous coincidences attract attention; the failures are disregarded or explained away. Probably the magician is never wholly an impostor, and frequently has a whole-hearted belief in himself; in this connexion may be noted the fact that jugglers tricks have in all ages been passed off as magical; the name of "conjuror" (q.v.) survives in our own day, though the conjurer no longer claims that his mysterious results are produced by demons. It is interesting to note that magical leechcraft depended for its success on the power of suggestion (q.v.), which is to-day a recognized element in medicine; perhaps other elements may have been instrumental in producing a cure, for there are cases on record in which European patients have been cured by the apparently meaningless performances of medicine-men, but an adequate study of savage medicine is still a desideratum.

Bibliography.—For a general discussion of magic with a list of selected works see Hubert and Mauss in "Religion" in La Grande encyclopédie: K. T. Preuss in Globus, vols. 86, 87; Mauss, L'Origine des pouvoirs magiques, and Hubert, La Réprésentation du temps (Reports of École pratique des hautes écoles, Paris). For general bibliography see, Hauck, Realencyklopädie, s. v. "Magie"; A. C. Haddon, Magic and Fetishism. J. G. T. Graesse's Bibliotheca magica is an exhaustive list of early works dealing with magic and superstition. For Australia see Spencer and Gillen's works, and A. W. Howitt, Native Tribes, For America see Reports of Bureau of Ethnology, vii. xvii. For India see W. C. Caland, Alhindisches Zaubert-web; and W. Crooke, Popular Religion; also V. Henry, La Magie. For the Malays see W. W. Skeat, Malay Magic. For Babylonia and Assyria see L. W. King's works. For magic in Greece and Rome see Daremberg and Saglio, s. v. "Magia," 2 Amuletum," &c. For medieval magic see A. Maury, La Magie. For illustrations of magic see J. G. Frazer, The Golden Bough; E. S. Hartland, Legend of Perseus; E. B. Tyler, Primitive Religion; W. S. Adams, Magic and Medicine. For the works of Frazer and Skeat cited above; also Journ. Anthrop. Inst. xxxvi. 92-103: Zeitschrift für Ethnologie (Verhandlungen) (1905), 153-162: Bulletin trimestriel de l'académie malgache, iii. 195-199. See also bibliography to TABOO and WITCHCRAFT.

(N. W. T.)

MAGIC SQUARE, a square divided into equal squares, like a chess-board, in each of which is placed one of a series of consecutive numbers from 1 up to the square of the number of cells in a side, in such a manner that the sum of the numbers in each row or column and in each diagonal is constant.

From a very early period these squares engaged the attention of mathematicians, especially such as possessed a love of the marvellous, or sought to win for themselves a superstitious regard. They were then supposed to possess magical properties, and were worn, as in India at the present day, engraved in metal or stone, as amulets or talismans. According to the old astrologers, relations subsisted between these squares and the planets. In later times such squares ranked only as mathematical curiosities; till at last their mode of construction was systematically investigated. The earliest known writer on the subject was Emanuel Moscopulus, a Greek (4th or 5th century). Bernard Frenicle de Bessy constructed magic squares such that if one or more of the encircling bands of numbers be taken away the remaining central squares are still magical. Subsequently Poignard constructed squares with numbers in arithmetical progression, having the magical summations. The later researches of Philippe de la Hire, recorded in the Mémoires de l'Académie Royale in 1705, are interesting as giving general methods of construction. He has there collected the results of the labours of earlier pioneers; but the subject has now been fully systematized, and extended to cubes.

Two interesting magical arrangements are said to have been given by Benjamin Franklin; these have been termed the "magic square of squares" and the "magic circle of circles." The first (Fig. 1) is a square divided into 256 squares, i.e. 16 squares along a side, in which are placed the numbers from 1 to 256. The chief properties of this square are (1) the sum of the 16 numbers in any row or column is 2056; (2) the sum of the 8 numbers in half of any row or column is 1028, i.e. one half of 2056; (3) the sum of the numbers in two half-diagonals equals 2056; (4) the sum of the four corner numbers of the great square and the four central numbers equals 1028; (5) the sum of the numbers in any 16 cells of the large square which themselves are disposed in a square is 2056. This square has other curious
properties. The "magic circle of circles" (fig. 2) consists of eight annular rings and a central circle, each ring being divided into eight cells by radii drawn from the centre; there are therefore 65 cells. The number 12 is placed in the centre, and the consecutive numbers 11 to 75 are placed in the other cells. The properties of this figure include the following: (1) the sum of the eight numbers in any ring together with the central number 12 is 360, the number of degrees in a circle; (2) the sum of the eight numbers in any set of radial cells together with the central number is 360; (3) the sum of the numbers in any four adjoining cells, either annular, radial, or both radial and two annular, together with half the central number, is 180.

Construction of Magic Squares.—A square of 5 (fig. 3) has adjoining it one of the eight equal squares by which any square may be conceived to be surrounded, each of which has two sides resting on adjoining squares, while four have sides resting on the surrounded square, and four meet it only at its four angles. 1, 2, 3 are placed along the path of a knight in chess; 4, along the same path, would fall in a cell of the outer square, and is placed instead in the corresponding cell of the original square; 5 then falls within the square. a, b, c, d are placed diagonally in the square; but e enters the outer square, and is removed thence to the same cell of the square it had left. a, b, γ, c, e pursue another regular course; and the diagram shows how that course is recorded in the square they have twice left. Whenever of the eight surrounding squares may be entered, the corresponding cell of the central square is taken instead. The 1, 2, 3, . . . a, b, c, . . ., a, b, c, . . ., a, b, c, . . ., a, b, c, . . ., are said to lie in "paths."

Squares whose Roots are Odd.—Figs. 4, 5, and 6 exhibit one of the earliest methods of constructing magic squares. Here the

3's in fig. 4 and 2's in fig. 5 are placed in opposite diagonals to secure the two diagonal summations; then each number in fig. 5 is multiplied by 5 and added to that in the corresponding square in fig. 4, which gives the square of fig. 6. Figs. 7, 8 and 9 give De la Hire's method; the squares of figs. 7 and 8, being combined, give the magic square of fig. 9. C. G. Bachet arranged the numbers as in fig. 10, where there are three numbers in each of four surrounding squares; these being placed in the corresponding cells of the central square, the square of fig. 11 is formed. He also constructed squares such that if one or more outer bars of numbers are removed the remaining central squares are magical. His method of forming them may be understood from a square of 5. Here each summation is 5ε3; if therefore 13 is subtracted from each number, the summations will be zero, and the twenty-five cells will contain the series ± 1, ± 2, ± 3, . . . ± 12, the odd cell having 0. The central square of 3 is formed with four of the twelve numbers with + and − signs and zero in the middle; the hand is filled up with the rest, as in fig. 12; then 13 being added in each cell, the magic square of fig. 13 is obtained.

Squares whose Roots are Even.—These were constructed in various ways, similar to that of 4 in figs. 14, 15 and 16. The numbers in fig. 15 being multiplied by 4, and the squares of figs. 14 and 15 being superimposed, give fig. 16. The application of this method to squares the half of whose roots are odd requires a complicated adjustment. Squares whose half root is a multiple of 4, and in which there are summations along all the diagonal

3's in fig. 14 and 2's in fig. 15 are placed in opposite diagonals to secure the two diagonal summations; then each number in fig. 15 is multiplied by 5 and added to that in the corresponding square in fig. 14, which gives the square of fig. 16. Figs. 17, 18 and 19 give De la Hire's method; the squares of figs. 17 and 18, being combined, give the magic square of fig. 19. C. G. Bachet arranged the numbers as in fig. 10, where there are three numbers in each of four surrounding squares; these being placed in the corresponding cells of the central square, the square of fig. 11 is formed. He also constructed squares such that if one or more outer bars of numbers are removed the remaining central squares are magical. His method of forming them may be understood from a square of 5. Here each summation is 5ε3; if therefore 13 is subtracted from each number, the summations will be zero, and the twenty-five cells will contain the series ± 1, ± 2, ± 3, . . . ± 12, the odd cell having 0. The central square of 3 is formed with four of the twelve numbers with + and − signs and zero in the middle; the hand is filled up with the rest, as in fig. 12; then 13 being added in each cell, the magic square of fig. 13 is obtained.

Nasik Squares.—Squares that have many more summations than in rows, columns and diagonals were investigated by A. H. Frost (Cambridge Math. Jour., 1857), and called Nasik squares, from the town in India where he resided; and he extended the method to cubes, various sections of which have the same singular properties. In order to understand their construction it will be necessary to
consider carefully fig. 21, which shows that, when the root is a prime, and not composite, number, as 7, eight letters a, b, ..., h may proceed from any, the same, cell, suppose that marked 0, each letter being repeated in the cells along different paths. These eight paths are called "normal paths," their numbers being one more than the root. Observe here that, excepting the cells from which any two letters start, they do not occupy the same cell, and that two letters, starting from any two different cells along different paths, appear together in the one and only one cell. Hence, if \( p \) be placed in the cells of one of the \( n+1 \) normal paths, each of the remaining \( n \) normal paths must contain at least one of these \( p \)’s. If now we fill each row with \( p, p, \ldots, p \) in the same order, commencing from the \( p \) in that row, the set of \( n+1 \) normal paths will be of the same path similar to that of \( p \), and each of the \( n \) normal paths will contain one, and only one, of the letters \( a, b, \ldots, p \), whose sum will be \( 2p \).

Similarly \( q \) be placed along any of the normal paths, different from that of the \( p \)'s, and each row filled as above with the letters \( g, q, g, \ldots, g \), the sum of the \( g \)'s along any normal path different from that of the \( g \) will be \( 2q \). The \( n^2 \) cells of the square will now be found to contain all the combinations of \( p^2 \) or \( q^2 \) or \( pq \) or \( a, b, \ldots, p, q \) or \( g, q, g, \ldots, g \). When the root is an odd composite number, as 9, 15, \&c., it will be found that in some paths, different from the two along which the \( p \) and \( g \) were placed, instead of having each of the \( p \)’s and \( g \)’s, some one single letter, \( s \), being common in every \( p \) and \( g \), there be on the one of \( q \), the triplets \( p, p, p, p, p, p, p, p, q, q, q, q, q, q, q, q \) and \( g, g, g, g, g, g, g, g \) occur, each triplet thrice, along paths whose sum will be \( 2p \) and \( 2g \) respectively. If now the \( q \)’s are multiplied by 0, and added to the \( p \)’s, the \( n \) square cells, we shall have a Nasik square, with constant sum along eight of its ten normal paths. In fig. 22 and in the nonary scale, that in the centre is the middle one of \( 1 \) to \( 9^2 \) and the sum of pairs of numbers equal to constant from this position to the central 45 is twice 45; and the sum of any number and the 8 numbers from it. Generally, and in the case of every column, the constant Nasik is equal to \( 2 \) and \( 32 \), 22, 76, 77, 26, 37, 56, 57. The numbers in fig. 22 being kept in the nonary scale, it is not necessary to add any nine of them to \( 1 \) to \( 9^2 \) so that every section of the cube by planes perpendicular to an edge has the properties of a Nasik square; also sections by planes perpendicular to a face, and passing through the cubical centres of any path of Nasik summation in that face. Fig. 25 shows by dots the way in which these cubes are constructed.

A dot is here placed on three faces of a cubelet at the corner, showing that this cubelet belongs to one of the faces AOB, BOC, COA, of the cube. Dots are placed on the cubelets of some path of AOB (here, the knight’s path), beginning from 0, also on the cubelets of a knight’s path in BOC. Dots are now placed in the cubelets of similar paths that on BOC in the other six sections parallel to BOC, starting from their dots in AOB. Forty-nine of the three hundred and forty-three cubelets will now contain a dot; and it will be observed that the dots in sections perpendicular to BO have arranged themselves in the same manner as \( p \), \( q \), \( r \). Being placed in the corner cubelet O, these letters were severally placed in the cubelets of three different paths of AOB, and again along any similar paths in the three sections perpendicular to AO, starting from the letter of position in AOB. Next, \( p, p, p, \ldots, p, q, q, r, r, r, \) are placed in the other cubelets of the edge AO, and dispersed in the same manner as \( p, q, r, r, \). Every cubelet will then be found to contain a different combination of the \( p \)'s, \( q \)'s and \( r \)'s. If therefore the \( p \)'s are made equal to 1, 2, 3, 4, 5, 6 in any order, and the \( q \)’s multiplied by 7, and the \( r \)’s by 7, then, as in the case of the squares, the \( 7^2 \) cubelets will contain the numbers from 1 to \( 7^2 \), and the Nasik summations will be \( 2q^2 + 2q + q + 2r \), and \( r + 2r + 2r \). If 2, 4, 5 be values of \( p, q, r \), the number for that cubelet is written 245 in the septenary scale, and if all the cubelets are kept thus, the paths along which summations are made will be without adding, as the seven numbers would contain 1, 2, 3, 4, 5, 6, 7 in each of the other places. In all Nasik cubes, if such values are given to the letters on the central cubelet that the number is the middle one of the series 1 to \( n^2 \), the sum of all the pairs of numbers opposite to and equidistant from the middle number is the double of it. Also, if around a Nasik cube the twenty-six surrounding equal cubes be placed with their cells filled with the same numbers, and their corresponding faces looking the same way,—and if the surrounding space be conceived to be divided by the central cube, and the eight lines of limited length be drawn through any two cubical centres, one in each of any two cubes,—the numbers along that line will be found to recur in groups of seven, which (except in the three cases where the same \( p, q, r \) recur in the group) together make a Nasik summation, e.g. 72 and 32, 22, 76, 77, 26, 37, 56, 57. The numbers in fig. 22 being kept in the nonary scale, it is not necessary to add any nine of them to \( 1 \) to \( 9^2 \) so that every section of the cube by planes perpendicular to an edge has the properties of a Nasik square; also sections by planes perpendicular to a face, and passing through the cubical centres of any path of Nasik summation in that face. Fig. 25 shows by dots the way in which these cubes are constructed.

</table>
cubes might be filled by the numbers from 1 to \(n^3\), and so ad infinitum. When the root is an odd composite number the values of the three groups of letters have to be adjusted as in squares, also in cubes of an even root. A similar process enables us to place successive numbers in the cells of several equal strips, as shown in 25 in which the Nasical summations are the same in each, as in fig. 25.

Among the many ingenious squares given by various writers, this article may justly close with two by L. Euler, in the Histoire de l'académie des sciences (Berlin, 1759). In fig. 27 the natural numbers show the path of a knight that moves within an odd square in such a manner that the sum of pairs of numbers opposite to and equidistant from the middle figure is its double. In fig. 28 the knight returns to its starting cell in a square of 6, and the difference between the path of the numbers opposite to and equidistant from the middle point is 18.

A model consisting of seven Nasik cubes, constructed by A. H. Frost, is in the South Kensington Museum. The centres of the cubes are provided with holes in a straight line, the surfaces looking the same way in a plane parallel to that line. Each of the cubes has seven parallel glass plates, to which, on one side, the seven numbers in the septenary scale are fixed, and behind each, on the other side, its value in the common scale. Thus, the middle number from 1 to 7, occupies the central cubelet of the middle cube. Besides each cube having separately the same Nasical summation, this is also obtained by adding the numbers in any seven similarly situated cublets, as shown in fig. 29. Also, the number of all pairs of equal numbers, in a straight line, through the central cube of the system, equidistant from it, in whatever cubes they are, is twice 1201.

**Fennell's Magic Ring.**—It has been noticed that the numbers of magic squares, of which the extension by repeating the rows and columns of \(n\) numbers so as to form a square of \(2n-1\) sides yields \(n^2\) magic squares of \(n\) sides, are arranged as if they were all inscribed round a cylinder and also inscribed on another cylinder at right angles to the first. C. A. M. Fennell explains this apparent anomaly by describing such magic squares as Mercator's projections, so to say, of "magic rings."

The surface of these magic rings is symmetrically divided into \(n^2\) quadrangular compartments or cells by \(n\) equidistant zonal circles parallel to the circular axis of the ring and by \(n\) transverse circles perpendicular to the surface of the ring. If the zones be divided, by the zones intersecting the zonal circles, the number of cells which are in common with the zone is equal to the number of the zone. The surface of a magic ring is divided into two equal sections when \(n\) is a prime number. The cells are equal if and only the diagonals of the ring contain the number \(n^2\), and without increment, i.e. the same sum as that of the numbers in each zone and each transverse section. But if \(n\) be 3 or a multiple of 3, only from 2 to \(n\) of the diagonal curves carry the sum in question, so that the sum of an imperfect ring, equal to the sum of the zone, can be arranged to make a perfect magic ring or magic square can also make an imperfect magic ring, e.g. the set 1 to 16 if the numbers 1, 6, 11, 16 lie thus on a diagonal curve instead of in the order 1, 6, 11, 16.

In fig. 27 the number of cells containing each, \(n^2\) distinct magic squares can be read off; as the four numbers round each intersection of a zonal circle and a transverse circle constitute corner numbers of a magic square. The shape of a magic ring being dependent on an indefinite extension of the number of the aforesaid \(n^2\) magic squares.

**MAGINN, WILLIAM** (1793–1842), Irish poet and journalist, was born at Cork on the 10th of July 1793. The son of a schoolmaster, he graduated at Trinity College, Dublin, in 1811, and after his father's death in 1813 succeeded him in the school. In 1810 he began to contribute to the Literary Gazette and to Blackwood's Magazine, writing as " R. T. Scott" and " Morgan O'Doherty." He first made his mark as a parodist and a writer of humorous Latin verse. In 1821 he visited Edinburgh, where he made acquaintance with the Blackwood circle. He is credited with having originated the idea of the Noces ambrosianae, of which some of the most brilliant chapters were his. His connexion with Blackwood lasted, with a short interval, almost to the end of his life. His best story was " Bob Burke's Duel with Ensign Brady." In 1832 he removed to London. He was employed by John Murray on the short-lived Representative, and was for a short time joint-editor of the Standard. But his temperate habits and his imperfect journalistic morality prevented any permanent success. In connexion with Hugh Fraser he established Fraser's Magazine (1836), in which appeared his "Homeric Ballads." Maginn was the original of Captain Shandon in Pendennis. In spite of his inexhaustible wit and brilliant scholarship, most of his friends were eventually alienated by his obvious failings, and his persistent insolvency. He died at Walton-on-Thames on the 21st of August 1842.

His Miscellanies were edited (5 vols., New York, 1855–1857) by R. Shelton Mackenzie and (2 vols., London, 1885) by R. W. Montagu [J. B. 1897].

**MAGISTRATE** (Lat. magistratus, from magister, master, properly a public office, hence the person holding such an office), was at first, one vested with authority to administer the law or one possessing large judicial or executive authority. In this broad sense the word is used in such phrases as the "first magistrate" of a king in a monarchy or "the chief magistrate" of the president of the United States. But it is more generally applied to minor or subordinate judicial officers, whether unpaid, as justices of the peace, or paid, as stipendiary magistrates. A stipendiary magistrate is appointed in London under the Metropolitan Police Acts 1839, in municipal boroughs under the Municipal Corporations Act 1882, and in particular districts under the Stipendiary Magistrates Act 1863 and special acts. In London and municipal boroughs a stipendiary magistrate must be a barrister of at least seven years' standing, while under the Stipendiary Magistrates Act 1863 he may be of five years' standing. A stipendiary magistrate may do all acts authorized to be done by two justices of the peace.

The term *magistratus* in ancient Rome originally implied the office of *magister* (master) of the Roman people, but was subsequently applied also to the holder of the office, thus becoming identical in sense with *magister*, and supplanting it in reference to any kind of public office. The fundamental conception of Roman magistracy is tenure of the *imperium*, the sovereignty which resides with the Roman people, but is by it conferred either upon a single ruler for life, as in the later monarchy, or upon a college of magistrates for a fixed term, as in the Republican period. The Roman theory of magistracy underwent little change when two consuls were substituted for the king; but the subdivision of magisterial powers which characterized the first centuries of the Republic, and resulted in the establishment of twenty annually elected magistrates of the people, implied some modification of this principle of the investiture of magistrates with supreme authority. For when the magistrates were multiplied a distinction was drawn between magistrates with *imperium*, namely consuls, praetors and occasionally dictators, and the remaining magistrates, who, although exercising independent magisterial authority and in no sense agents of the higher magistrates, were invested merely with *potestas* (powers) to assist in the administration of the state. At the same time the actual authority of every magistrate was weakened not only by his colleagues' power of veto, but by the power possessed by any magistrate of quashing the act of an inferior, and by the tribune's right of putting his veto on the act of any magistrate except a dictator; and the subdivision of authority, which placed a great deal of business in the hands of young and inexperienced magistrates, further tended to increase the actual power as well as the influence of the senate at the expense of the magistracy.

In the developed Republican magistracies were divided into two classes: (a) magistrates of the whole people (populi Romanii) and (b) magistrates of the plebs. The former class is again divided into two sections: (a) curule and (b) non-curule, a distinction which rests mainly on dignity rather than on actual power, for it cuts across the division of magistrates according to their tenure or non-tenure of *imperium*.
The magistrates of the people—also known as patrician magistrates, probably because the older and more important of these magistrates could originally be held only by patricians (p. 309)—were: (a) Dictator, master of the horse (see Dictator), consuls, praetors, curule, aediles and censors (curule); and (b) Quaestors, and the body of minor magistrates known as curiae (non-curule). The dictatorship and consulship were as old as the Republic. The first praetor was appointed in 366 B.C., a second was added in 242 B.C., and the number was gradually increased for provincial government until Sulla, who was already very powerful at the time, doubled it. In the early Republic it grew to eighteen. Censors were first instituted in 443 B.C., and the office continued unchanged until its abolition by Sulla, after which, though restored, it rapidly fell into abeyance. Curule aediles were instituted at the same time as the praetorship, and continued to exist until the fall of the Republic. The quaestorship was first held as old as the Republic, but the number rose during the Republic from two to twenty. All these offices except the censorship continued for administrative purposes during the principate, though shorn of all important powers.

b. The plebeian magistrates had their origin in the succession of the plebs to Mons Sacer in 494 B.C. (see Rome: History). In that year tribunes of the plebs were instituted, and two aediles were given them as subordinate officials, who were afterwards known as plebeian aediles, to distinguish them from the curule magistrates of the same name. Both these offices were abolished during the decemvirate, but were restored in 449 B.C., and survived into the principate.

The powers possessed by all magistrates alike were two:—
that of enforcing their enactments (coercitio) by the exercise of any punishment short of capital, and that of veto (intercessio) of any act of a colleague or minor magistrate. The right of summoning and presiding over an assembly of that body of citizens with whose powers the magistrate was invested lay with the higher magistrates only in each class, with the consuls and praetors, and with the tribunes of the plebs. Civil jurisdiction was always a magisterial prerogative at Rome, and criminal jurisdiction also, except in capital cases, the decision of which was vested in the people at least as early as the first year of the Republic, was wielded by magistrates until the establishment of the various quaestiones perpetuae during the last century of the Republic. But in civil cases the magistrate, though controlling the trial and deciding matters of law, was quite distinct from the judge or body of judges who decided the question of fact, and the quaestiones perpetuae, which reduced the magistrate in criminal cases to a mere president of the court, gave him a position of least authority. But in this respect the praetor, who tried civil cases only in so far as the praetor controlled the trial in some degree by his formula, under which the judges decided the question of fact. Tenure of magistracy was always held to depend upon election by the body whose powers the magistrate wielded. Thus the magistrates of the plebs were elected by the plebeian council, those of the people in the Comitia (q.v.). In every case the outgoing magistrates, as presiding officer of the elective assembly, exercised the important right of nominating his successor for election.

See A. H. J. Greenidge, Roman Public Life, 152 seq., 350 seq. (London, 1901); T. Mommsen, Römisches Staatsrecht, t. 11, i. (1887).

(A. M. Cl.)

MAGLIAECHI, ANTONIO DA MARCO (1633-1714), Italian bibliophile, was born at Florence on the 28th of October 1633. He followed the trade of a goldsmith until 1673, when he received the appointment of librarian to the grand-duke of Tuscany, a post for which he had qualified himself by his vast stores of self-acquired learning. He died on the 4th of July 1714, bequeathing his large private library to the grand-duke, who in turn handed it over to the city.

MAGLIA, AGOSTINO (1824-1891), Italian financier, was a native of Lanzo, near Salerno. He studied at Naples, and a book on the philosophy of law based on Liberal principles won for him a post in the Neapolitan treasury. He entered the Italian Senate in 1871, and had already secured a reputation as a financial expert before his Questione monetaria appeared in 1874. In December 1877 he became minister of finance in the reconstructed De pretis ministry, and he subsequently held the same office in three other Liberal cabinets. In his second tenure he carried through (1880) the abolition of the grist tax, to take effect in 1884. Having to face an increased expenditure without offending the Radical electorate by unpopular taxes, he had recourse to unsound methods of finance, which seriously embasement Italian credit for some years after he finally laid down office in 1888. He died in Rome on the 22nd of February 1891. He was one of the founders of the anti-socialistic "Adam Smith Society" in the last years of the 19th century.

MAGNA CARTA, or the Great Charter, the name of the famous charter of liberties granted at Runnymede in June 1215 by King John to the English people. Although in later ages its importance was enormously magnified, it differs only in degree, not in kind, from other charters granted by the Norman and early Plantagenet kings. Its greater length, however, still more the exceptional circumstances attending its birth, gave to it a position absolutely unique in the minds of later generations of Englishmen. This feeling was fostered by its many confirmations, and in subsequent ages, especially during the time of the struggle between the Stuart kings and the parliament, it was regarded as something sacrosanct, embodying the very ideal of English liberties, which to some extent had been lost, but which must be regained. Its provisions, real and imaginary, formed the standard towards which Englishmen must strive.

The causes which led to the grant of Magna Carta are described in the article on English History. Briefly, they are to be found in the conditions of the time; the increasing insularity of the English barons, now no longer the holders of estates in Normandy; the substitution of an unpopular for a popular king, an active spur to the rising forces of discontent; and the unprecedented demand for money, the demands followed, not by honour, but by dishonour, to the arms of England abroad. So much for the general causes. The actual crisis may be said to begin with the quarrel between John and Pope Innocent III. regarding the appointment of a new archbishop to the see of Canterbury. This was settled in May 1213, and in the new prelate, the papal nominee, Stephen Langton, who landed in England and absolved the king in the following July, the baronial party found an able and powerful ally. But before this event John had instituted a great inquiry, the inquest of service of June 1212, for the purpose of finding out how much he could exact from each of his vassals, a measure which naturally excited some alarm; and then, fearing a baronial rising, he had abandoned his proposed expedition into Wales, had taken hostages from the most prominent of his foes, and had sought safety in London.

His abdication followed, and then he took courage. Turning once more his attention to the recovery of Normandy, he asked the barons for assistance for this undertaking; in reply they, or a section of them, refused, and instead of crossing the seas the king marched northwards with the intention of taking vengeance on his disobedient vassals, who were chiefly barons of the north of England. Langton followed his sovereign to Northampton and persuaded him, at least for the present, to refrain from any serious measures of revenge. Before this interview a national council had met at Runnymede, on the last day of the month of August 1215, and this was followed by another council, held in St. Paul's church, London, later in the same month; it was doubtless summoned by the archbishop, and was attended by many of the higher clergy and a certain number of the barons. Addressing the gathering, Langton referred to the laws of Edward the Confessor as "good laws," which the king ought to observe, and then mentioned the charter granted by Henry I. on his accession as a standard of good government. This event has such an important bearing on the issue of Magna Carta that it is not inappropriate to quote the actual words used by Matthew Paris in describing the incident. The chronicler represents the archbishop as saying "Inventa est quoque nunc carta quaedam Henrici primi regis Angliae per quam, si volueritis, libertates diu amissas potestis ad statum pristinum revocare." Those present decided to contend for the death for their "long-lost liberties," and with this the meeting came to an end. Nothing, however, was done during the remainder of the year, and John, feeling his position had grown stronger, went abroad early in 1214, and remained for some months in France. With his mercenaries behind him he met with some small successes in his fight for Normandy, but on the 27th of July he and his ally, the emperor Otto IV., met with a crushing
defeat at Bouvines at the hands of Philip Augustus, and even the king himself was compelled to recognise that his hopes of recovering Normandy were at an end.

Meanwhile in England, which was ruled by Peter des Roches as justiciar, the discontent had been increasing rather than diminishing, and its volume became much larger owing to an event of May 1214. Greatly needing money for his campaign, John ordered another scutage to be taken from his tenants; this, moreover, was to be at the unprecedented rate of three marks on the knight's fee, not as on previous occasions of two marks, although this latter sum had hitherto been regarded as a very high rate. The northern barons refused to pay, and the gathering forces of resistance received a powerful stimulus when a little later came the news of the king's humiliation at Bouvines. Then in October the beaten monarch returned to England, no course open to him but to bow before the storm. In November he met some of his nobles at Bury St Edmunds, but as they still refused to pay the scutage no agreement was reached. At once they took another step towards the goal. With due solemnity (super majus allokre) they swore to withdraw their allegiance from the king and to make war upon him, unless within a stated time he restored to them their rightful laws and liberties. While they were collecting troops in order to enforce these threats, John on his part tried to divide his enemies by a concession to the clerical section. By a charter, dated the 21st of November 1214, he granted freedom of election to the church. However, this did not prevent the prelates from continuing to act to some extent with the barons, and early in January 1215 the malcontents asked the king to confirm the laws of Edward the Confessor and the other liberties of the kingdom. He evaded the request and secured a truce until Easter was passed. Energetically making use of this period of respite, he again issued the charter to the church, ordered his subjects to take a fresh oath of allegiance to him, and sent to the pope for aid; but neither these precautions, nor his expedient of talking the barons out of the desire to renew the truce, nor his promise to the pope, had the desired effect. In April they met in arms at Stamford, and as soon as the truce had expired they marched to Brackley, where they met the royal ministers and again presented their demands. They were carried to the king at Oxford, but angrily he refused to consider them. Then the storm burst. On the 5th of May the barons formally renounced their allegiance to John, and appointed Robert Fitzwalter as their leader. They marched towards London, while John made another attempt to delay the crisis, or to divide his foes, by granting a charter to the citizens of London (May 9, 1215), and then by offering to submit the quarrel to a court of arbitrators under the presidency of the pope. But neither the one nor the other expedient availed him. Arbitration under such conditions was contemptuously rejected, and after the king had ordered the sheriffs to seize the lands and goods of the revolting nobles, London opened its gates and peacefully welcomed the baronial army. Other towns showed also their sympathies were with the insurgents, and John was forced to his knees. Promising to assent to their demands, he agreed to meet the barons, and the gathering was fixed for the 15th of June, and was to take place in a meadow between Staines and Windsor, called Runnymede.

At the famous conference, which lasted from Monday the 15th to Tuesday the 23rd of June, the hostile barons were present in large numbers; on the other hand John, who rode over each day from Windsor, was only attended by a few followers. At once the malcontents presented their demands in a document known popularly as the Articles of the Barons, more strictly as Capitula quae barones petunt et dominus rex concedit. Doubtless this had been drawn up beforehand, and was brought by the baronial leaders to Runnymede; possibly it was identical with the document presented to the royal ministers at Brackley a few weeks before. John accepted the Articles on the same day and at once the great seal was affixed to them. They are forty-eight in number, and on them Magna Carta was based, the work of converting them into a charter, which was regarded as a much more binding form of engagement, being taken in hand immediately. This duty occupied three days, negotiations between the two parties taking place over several disputed points, and it was completed by Friday the 19th, when several copies of the charter were sealed. All then took an oath to keep its terms, and orders were sent to the sheriffs to publish it, and to see that its provisions were observed, two or three days being taken up with making and sending out copies for this purpose. It should be mentioned that, although the charter was evidently not sealed until the 19th, the four existing copies of it are dated the 15th, the day on which John accepted the articles.

The days between Friday the 19th and the following Tuesday, when the conference came to an end, were occupied in providing, as far as possible, for the due execution of the reforms promised in the king in Magna Carta. The document itself provided for an elected committee of twenty-five barons, whose duty was to compel John, by force if necessary, to keep his promises; but this was evidently regarded as insufficient, and the matter was dealt with in a supplementary treaty (Conventio facta inter regem Angliae et barones ejusdum regni). As a guarantee of his good faith John gave up and surrendered the fortune London to his foes, while the Tower was entrusted to the neutral keeping of the archbishop of Canterbury. John then asked the barons for a charter that they on their part would keep the peace. This was refused, and although some of the bishops entered a mild protest, the question was allowed to drop. Regarding another matter also, the extent of the royal forests, the prelates made a protest. John and his friends feared lest the inquiry promised into the extent of the hated forest areas would be carried out too rigorously, and that these would be seriously curtailed, if not abolished altogether. Consequently, the two archbishops and their colleagues declared that the articles in the charter which provided for this inquiry, and for a remedy against abuses of the forest laws by the king, must be interpreted in too harsh a spirit. The customs necessary for the preservation of the forests must remain in force.

In the meantime the barons would bind John. Even before Magna Carta was signed he had set to work to destroy it, and he now turned to this task with renewed vigour. He appealed to the pope, and hoped to crush his enemies by the aid of foreign troops, while the barons prepared for war, and the prelates strove to keep the peace. Help came first from the spiritual arm. On the 24th of August 1215 Innocent III. published a bull which declared Magna Carta null and void. It had been extorted from the king by force (per vim et metum), and in the words of the bull the pope said "compositionem hujusmodi reprobamus pentitus et damna
damus." He followed this up by excommunicating the barons who had obtained it, and in the autumn of 1215 the inevitable war began. Capturing Rochester castle, John met with some other successes, and the disheartened barons invited Louis, son of Philip Augustus of France and afterwards king as Louis VIII., to take the English crown. In spite of the veto of the pope Louis accepted the invitation, landed in England in May 1216, and occupied London and Winchester. The king, having been called away in the meantime turned against John. The “ablest and most ruthless of the Angevins,” as J. R. Green calls this king, had not, however, given up the struggle, and he was still in the field when he was taken ill, dying in Newark castle on the 19th of October 1216.

In its original form the text of Magna Carta was not divided into chapters, but in later times a division of this kind was adopted. This has since been retained by all commentators, the number of chapters being 63.

The preamble states that the king has granted the charter on the advice of various prelates and barons, some of whom, including the archbishop of Canterbury, the papal legate Pandulf, and William Marshal, earl of Pembroke, are mentioned by name.

Chapter I. declares that the English church shall be free and shall enjoy freedom of election. This follows the precedent set in the accession charter of Henry I. and in other early charters, although it had no place in the Articles of the Barons. On the present occasion it was evidently regarded as quite a formal and introductory matter, and the same remark applies to the general grant of liberties to freemen and their heirs, with which the chapter concludes.
Then follows a series of chapters intended to restrain the king from raising money by the harsh and arbitrary methods adopted in the past. These chapters, however, only afforded protection to the tenants-in-chief, the crown, and it is clear from their progressive position that the framers of the charter regarded them as of paramount importance.

Chapter II., fixes the amount of the relief to be paid to the king by the tenants-in-chief in various sums. Previously John, disregarding the custom of the past, had taken as much as he could extort. Hence-forward he who inherits a barony must pay £100, he who inherits a knight’s fee 100 shillings or less, and for smaller holdings less according to the amount of fees.

Chapters III. to VI. deal with the abuses of the king’s privilege of acting as guardian of minors and their lands. Money must not be extorted from a ward when he receives his inheritance. The guardian must not take from the ward’s property more than a reasonable amount for his expenses and the like; on the contrary he must maintain the houses, estates and other belongings in a proper state of efficiency. A ward must be allowed a reasonable liberty of the marriage. He or she must not be married so often as the case in the past, be forced to marry some royal favourite, or some one who had paid a sum of money for the privilege.

Chapters VII. and VIII. are for the protection of the widows of tenants-in-chief. On the death of her husband a widow must receive her husband’s inheritance, without delay, except to the citizens of London and of other places without the consent of the council. This provision was omitted from Magna Carta. It was not found of interest, but it does illustrate the growing power of the council; and were the citizens of London, while the three recognized aids shall only be levied at a reasonable rate. In dealing with this matter the Articles of the Barons declared that the aids and subsidies taken from the citizens of London and of other places without the consent of the council. This provision was omitted from Magna Carta, except so far as it related to aids from the citizens of London. This chapter does not give the people the right to control taxation. It gives to the people the right to control over the manner of taxation, and protects one class only from arbitrary exactions, and that class the most powerful and the most wealthy.

Chapter XIII. gives to the citizens of London all their ancient liberties and free customs.

Chapter XIV., provides for the assembly of the council when its consent is necessary for raising an aid or a scutage. Individual summonses must be sent to the prelates and greater barons, while the lesser barons shall be called together through the sheriffs and bailiffs. At least forty days’ notice of the meeting must be given, and the cause thereof specified. No chapter corresponding to this is found in the Articles and none was inserted in the issues of Magna Carta. It was a step forward, and does mark an advance in the history of parliament, as it merely expresses the customary method of summoning a council. It does not, as has been sometimes asserted, in any way establish a representative system.

Chapter XV. extends the concessions obtained by the greater barons for themselves to the lesser landholders, the tenants of the tenants-in-chief.

Chapter XVI. declares that those who owe military service for their lands shall not be called upon to perform more than the due amount of such service.

We now come to an important series of articles which relates with abuses in the administration of justice. Henry II. made the royal courts of law a lucrative source of revenue, but he gave protection to suits. Under his sons justice was equally, perhaps more, costly, while adequate protection was much harder to obtain. Here were many grievances, and the barons set to work to redress them.

Chapter XVII. declares that common pleas must henceforward be heard in a fixed place. This had already been to some extent the practice when this class of cases was heard; it was now made the rule. From this time suits in this court were not put to the expense and inconvenience of following the king from place to place.

Chapters XVIII. and XIX. deal with the three petty assizes, three kinds of cases regarding disputes about the possession of land. These must be heard in the county courts before two visiting justices and four knights of the shire. The hardship of attendance at the county courts was thus removed.

Chapters XX. to XXII. regulate the amount of fines imposed for offences against the law. Property necessary for one’s livelihood must not be taken. The fines must only be imposed by the oath of honest men of the neighbourhood. In the same way early and frequent trials must be held. But the real conception of justice is extended to the clergy, who, moreover, were not to be fined in accordance with the value of their benefices, but only of their other property. It should be noticed that trial by one’s peers, as understood in Magna Carta, is not confined to the nobility; in every class of society an accused man is punished in accordance with the verdict of his peers, or equals.

Chapter XXIII. asserts that persons shall not be compelled to move to any place against their will, unless the king do so on ancient custom. John had oppressed his subjects in this way before he visited a district for purposes of sport, and the hardship was a real one.

Chapter XXIV. declared that the sheriffs and other officers of the king must not hold the pleas of the crown. This was intended to give a man liberty of trial, who, in the former system, a sinner by his imprisonment had incurred a very bad reputation by their methods of administering justice.

Chapter XXV. also concerns the sheriffs. It prevents the king from increasing by their agency the amount of money annually due to him from the various counties and hundreds. The custom was that a sheriff might get a crown’s suit out of the common wealth, this being called the firma comitalis, and for the sheriff to collect this as best he could. Henceforward this amount must not be raised.

Chapters XXVI. and XXVII. were intended to protect the property of deceased persons, and the labourers. Castle and grange were the liability incurred by the holders of such lands, and the king of some estates to serve in the garrison of the royal castles. The constables of these castles had adopted the custom of compelling these landholders to give money and not service, mercenaries being then used to perform these duties.

Chapters XXX. and XXXI. forbid the royal officials to seize the horses or carts of freemen for transport duty, or to take wood for the king’s buildings.

Chapter XXXII. says knights must not be compelled to give money instead of performing castle-gard, if they are willing to perform this service according to custom. Castles and garrisons were the liability incurred by the holders of such lands, and the king of some estates to serve in the garrison of the royal castles. The constables of these castles had adopted the custom of compelling these landholders to give money and not service, mercenaries being then used to perform these duties.

Chapters XXXII. says that the lands of convicted felons shall be seized. Under the reign of such lands not kept for the king beyond a year and a day. In cases of treason the king had a right to the forfeited lands, but he was not allowed to establish a similar right in cases of felony.

Chapter XXXIII. provided for the removal of kylleys, or weirs, from all English rivers. This was intended to give greater freedom to inland navigation, the rivers being the main highways of trade.

Chapter XXXIV. limits the use of the writ known as Pracea. This writ was one transferring cases concerning the ownership of property from the common law courts to the chancery courts. The custom, which owes its origin to Henry II., meant a loss of revenue to the lords, whose victory in this matter, however, was a step backwards. It checked temporarily the process of centralizing the administration of justice.

Chapter XXXV. provides for the uniformity of weights and measures throughout the kingdom.

Chapter XXXVI. promises that in future writs of inquisition shall be granted freely without payment of any kind. This kind of writ enabled a person to test the validity of an inference to the verdict of his neighbours instead of proving his innocence by the duel. This custom, which owes its origin to Henry II., meant a loss of revenue to the lords, whose victory in this matter, however, was a step backwards. It checked temporarily the process of centralizing the administration of justice.

Chapter XXXVII. prevents the king from administering certain kinds of land when these fall into the possession of minors. In the past John had evidently stretched his authority and seized lands over which others had really the right of possession.

Chapter XXXVIII. prevents a bailiff from compelling an accused man to submit to the ordeal without the approval of credible witnesses.

Chapter XXXIX. is more important and the English rendering of it may be given in full. No Freeman shall be arrested, or detained in prison, or deprived of his freedom, or outlawed, or banished, or in any way molested; and we will not set forth against him, nor send against him, unless by the lawful judgment of his peers, and by the verdict of the land. The object of this was clearly to restrain John from arbitrary proceedings against his free subjects. The principle
of judgment by one's peers is asserted, and is obviously the privilege of every class of freemen, not of the greater lords alone.

Chapter XL. simply says, 'To no one will we sell, to no one will we refuse or delay, right or justice.'

Chapter XLII. grants permission to merchants, both English and foreign, to enter and leave the kingdom, except in time of war. They are not to pay "evil tolls." The privilege is extended to all travellers, except the prisoner and the outlaw, and natives of a country under the king's jurisdiction is at liberty to go abroad.

Chapter XI. is intended to compel the king to refrain from exacting greater dues from an escheated barony than were previously due from such barony.

Chapter XVI. deals with the hated and oppressive forest laws. In future attendance at the forest courts is only obligatory on those who have business thereat.

Chapter XVII. says that the royal officials must know something of the law and the customs of their districts.

Chapter XXI. and XX. are speeches of thirty-five of the barons concerning the arrival of the early contributors.

Chapter XXII. says that certain royal minions, who are mentioned by name, are to be removed from their offices.

Chapter XXIII. says that as soon as peace is made all foreign mercenaries are to be banished.

Chapter XXII. and XXIII. are those in which the king promises to make amends for the injuries he has done to his barons in the past. He will restore lands and castles to those who have been deprived of them without the judgment of their peers; he will do the same concerning property unlawfully seized by Henry II. or Richard I. and now in his hands. In the latter case, however, he was allowed a respite until he returned from the projected crusade. He promises also to remove the forests, abbeys and the wardship of lands which belong lawfully to others.

Chapter XXIV. provides for the restoration of hostages. John had been in the habit of taking the children of powerful subjects as pledge for the behaviour of their fathers.

Chapter XXV. and XXVI. deal with the grievances of Welshmen. Restoration of property is promised to them practically in the same way as to the Anglo-Saxons.

Chapter XXVII. and XXVIII. are the charters of lands, and in the marches the law of the marches is to be employed.

Chapter XXIX. promises that his hostages and his charters shall be restored to Llewellyn, prince of Wales.

Chapter XXX. is a restatement of hostages to Alexander I., king of Scotland. Right is also to be done to him concerning the lands which he holds in England.

Chapter XIV. is a general statement that the aforesaid customs and liberties shall be observed by all classes. For instance, the provisions in Magna Carta concerning the freedom of the church find no place in the Articles, while a comparison between the two documents suggests that in other ways also influences favourable to the church and the clergy were at work while the famous charter was being framed. When one reflects how active and prominent Langton and other prelates were at Runnymede the change is not surprising. Another difference between the two documents concerns the towns and the trading classes. Certain privileges granted to them in the Articles are not found in Magna Carta, although, it must be noted, this document bestows exceptionally favoured treatment on the citizens of London. The conclusion is that the friends of the towns and the traders were less in evidence at Runnymede than they were at the earlier meetings of the barons, but that the neighbouring Londoners were strong enough to secure a good price for their support.

Magna Carta throws much light on the condition of England in the early 13th century. By denouncing the evil deeds of John and the innovations practised by him, it shows what these were and how they were hated; how money had been raised, how forest areas had been extended, how minors and widows had been cheated and oppressed. By declaring, as it does, what were the laws and customs of a past age wherein justice prevailed, it shows what was the ideal of good government formed by John's prelates and barons. Magna Carta can hardly be said to have introduced any new ideas. As Pollock and Maitland (History of English Law) say "on the whole the charter contains little that is absolutely new. It is restorative." But although mature study has established the truth of this proposition it was not always so. Statesmen and commentators alike professed to find in Magna Carta a number of political ideas which belonged to a later age, and which had no place in the minds of its framers. It was regarded as having conferred upon the nation nothing less than the English constitution in its perfect and completed form.

Sir Edward Coke finds in Magna Carta a full and proper legal answer to every exaction of the Stuart kings, and a remedy for every evil suffered at the time. Sir William Blackstone is almost equally admiring. Edmund Burke says "Magna Carta, if it did not give us originally the House of Commons, gave us at least a Hobbesian Constitution, a redress of wrong and consequence." Lord Chancellor used words equally superlative. "Magna Carta, the Petition of Rights and the Bill of Rights form that code, which I call the Bible of the English Constitution." Modern historians, although less rhetorical, speak in the highest terms of the importance of Magna Carta, the view of most of them being summed up in the words of Dr Stubbs: "The whole of the constitutional history of England is a commentary on this charter."

Many regard Magna Carta as giving equal rights to all Englishmen. J. R. Green says "The rights which the barons claimed for themselves they claimed for the nation at large." As a matter of fact this statement is only true with large limitations. The villains, who formed the majority of the population, got very little from it; in fact the only clauses which protect them do so because they are property—the property of their lords—and therefore valuable. They get neither political nor civil rights under Magna Carta. The traders, too, get little, while preferential treatment is meted out to the great landholders. Its benefits are confined to freemen, and of the benefits the lion's share fell to the larger landholders; the smaller landholders getting, it is true, some crumbs from the table. It did not establish freedom from arbitrary arrest, or the right of representatives of the people to control taxation, or trial by jury, or other conceptions of a later generation.

The story of Magna Carta after the death of John is soon told. On the 11th of November 1216 the regent William Marshal, earl of Pembroke, reissued the charter in the name of the young king Henry III. But important alterations were made. War was being waged against Louis of France, and the executive must not be hampered in the work of raising money; moreover the personal equation had disappeared, the barons did not need to protect themselves against John. Consequently the chapter limiting the power of the crown to raise seights and aids without the consent of the council vanished, and with it the complementary one which determined the method of calling a council.

Other provisions, the object of which had been to restrain John from demanding more money from various classes of his subjects,
were also deleted, and the same fate befell such chapters as dealt with more temporary matters. The most important of these was Chapter LXI., which provided for the appointment of 25 executors to compel John to observe the charter. The next year peace was made at Lambeth (Sept. 11, 1217) between Henry III. and Louis and another reissue of the charter was promised. This promise was carried out, but two charters appeared, one being a revised issue of Magna Carta proper, and the other a separate charter dealing with the forests, all references to which were omitted from the more important document. The date of this issue appears to have been the 6th of November 1217. The issue of a separate forest charter at this time led subsequently to some confusion. Roger of Wendover asserts that John issued a separate charter of this kind when Magna Carta appeared. This statement was believed by subsequent writers until the time of Blackstone, who was the first to discover the mistake.

As issued in 1217 Magna Carta consists of 47 chapters only. It declares that henceforward scutages shall be taken according to the precedents of Henry II.'s reign. New provisions were introduced for the preservation of the peace, unlawful castles were pulled down, and it was made unlawful to make the administration of justice by the visiting justices less burdensome. With regard to the land and the services due therefrom a beginning was made of the policy which culminated in the statutes of Mortmain and of Quia Emptores. The sheriffs were ordered to publish the revised charter on the 22nd of February 1218. Then in February 1225 Henry III. again issued the two charters with only two slight alterations, and this is the final form taken by Magna Carta, this text being the one referred to by Coke and the other early commentators. Subsequently the charters were confirmed several times by Henry III. and by Edward I., the most important occasion being their confirmation by Edward at Ghent in November 1297. On this occasion some supplementary articles were added to the charter; these were intended to limit the taxing power of the crown.

There are at present in existence four copies of Magna Carta, sealed with the great seal of King John, and several unsealed copies. Of the four two are in the British Museum, the possession of the Museum with the valuable collection of papers which had belonged to Sir Robert Cotton, who had obtained possession of both. One was found in Dover castle about 1630. This was damaged, and one of the documents, unique had been unsealed copies belong to the cathedrals of Lincoln and of Salisbury. Both were written evidently in a less hurried fashion than those in the British Museum, and the one at Lincoln was regarded as the most correct. Both Imperial commissioners were made to sign the appearance of the Statutes of the Realm in 1810. The British Museum also contains the original parchment of the Articles of the Barons. Magna Carta was first printed by Richard Pynson in 1499. This, however, was not the original text, which was neglected until the time of Blackstone, who printed the various issues of the charter in his book The Great Charter and the Charter of the Forest (1759). The earliest commentator of note was Sir Edward Coke, who published his Commentaries, with deals with Magna Carta, before the Long Parliament in 1642. Modern commentators, who also printed the various texts of the charter, are Richard Thomson, An Historical Essay on the Magna Carta of King John (1859); C. Bénot, in his Charles des libertés anglaises (1862); and W. Stubbs in his History of England (1883 and 1903). More recent books and one embodying 23 results of the latest research is W. S. McKechnie, Magna Carta (1905).

The text of Magna Carta is also printed in the Statutes of the Realm (1810–1828), and in T. Rymer's Foedera (1816–1869). In addition to these, besides the latter, there are other lists of the charters, which may be consulted: John Reeves, History of English Law (1783–1784); L. O. Pike, A Constitutional History of the House of Lords (1894); W. Stubbs, Constitutional History of England (1897); Sir F. Pollok and J. A. C. H. Hulme, The History of English Law (1907); and Holdsworth, A History of English Law (1903), and Kate Norgate, John Lackland (1902).

Magna Graecia (Μαγνὴ Παρθενία), the name given (first, apparently, in the 6th century B.C.) to the group of Greek cities along the coast of the "toe" of South Italy (or more strictly those only from Tarentum to Locri, along the east coast), while the people were called Italiotes (Ἰταλιῶται). The interior, which the Greeks never subdued, continued to be in the hands of the Bruttii, the native mountaineers, from whom the district was called Roman times (Βραττία also in Greek writers).

The Greek colonies were established first as trading stations, which grew into independent cities. At an early time a trade in copper was carried on between Greece and Teosensia (Homer, Od. i. 181). The trade for a long time was chiefly in the hands of the Euboeans; and Cyme (Cumae) in Campania was founded in the 8th century B.C., when the Euboean Cyme was still a great city. After this the energy of Chalcis went onward to Sicily, and the states of the Corinthian Gulf carried out the colonization of Italy, Rhetium having been founded, it is true, by Chalcis, but after Messana (Zancle), and at the request of the inhabitants of the latter. Sybaris (721) and Croton (703) were Achaean settlements; Locri Epizephyrii (about 710) was settled by Ozolian Locrians, so that, had it not been for the Dorian colony of Tarentum, the southern coast of Italy would have been entirely occupied by a group of Achaean cities. Tarentum (whether or not founded by pre-Dorian Greeks—its founders bore the unexplained name of Parthenae) became a Laconian colony at some unknown date, whence a legend grew up connecting the Parthenaei with Sparta, and 707 B.C. was assigned as its traditional date. Tarentum is remarkable as the only foreign settlement made by the Romans. It was industrial, depending largely on the purple and pottery trades, and in the 5th century B.C. the Greek invasion founded Siris about 650 B.C., and, much later, Elea (which was founded by Greek colonists from Crotone) from 580 B.C.

The Italic colonies were planted among friendly, almost kindred, races, and grew much more rapidly than the Sicilian Greek states, which had to contend against the power of Carthage. After the Achaean cities had combined to destroy the Ionic Siris, and had founded Metapontum as a counterpoise to the Dorian Tarentum, there seems to have been little strife among the Italiotes. An amphictyonic league, meeting in common rites at the temple of Hera on the Lacinian promontory, fostered a feeling of unity among them. The Pythagorean and Eleatic systems of philosophy had their chief seat in Magna Graecia. Other departments of literature do not seem to have been so much cultivated among them. The poet Ibycus, though a native of Rhegium, led a very wandering life. They sent competitors to the Olympic games (among them the famous Milo of Crotone); and the physicians of Croton early in the 6th century (especially in the person of Democedes) were reputed the best in Greece; but politically they appear to have generally kept themselves separate. One ship of Syracuse, however, the Iolaus, is said to have plundered the Siris, and its commander, a Syracuse, was said to have been on the side of the Greeks in the war. The Syracusan ship was named the Iolaus. The Syracusan ship was also said to have been on the side of the Greeks in the war. In the 6th century B.C., Tarentum remained neutral in 425. Foreign enemies pressed heavily on it. The Lucanians and Bruttians on the north captured one town after another. Dionysius of Syracuse attacked them from the south; and after he defeated the Crotonian league and destroyed Caulonia (386 B.C.), Tarentum remained the only powerful city. Henceforth the history of Magna Graecia is only a record of the vicissitudes of Tarentum (q.v.). Repeated expeditions from Sparta and Epirus tried in vain to prop up the decaying cities against the Greeks; and when in 282 the Romans appeared in the Tarentine Gulf the end was close at hand. The aid which Pyrrhus brought did little good to the Tarentines, and his final departure in 274 left them defenceless. During these constant wars the Greek cities had been steadily decaying; and in the second Punic war, when most of them seized the opportunity of revolting from Rome, their very existence was in some cases annihilated. Malaria increased in strength as the population diminished. We are told by Cicero (De am. 4), Magna Graecia nunc quidem deleta est. Many of the cities completely disappeared, and hardly any of them were of great importance under the Roman empire; some, like Tarentum,
maintained their existence into modern times, and in these only (except at Locri) have archaeological investigations of any importance been carried on; so that there still remains a considerable field for investigation.

(T. As.)

MAGNATE (Late Lat. magnus, a great man), a noble, a man in high position, by birth, wealth or other qualities. The term is specifically applied to the members of the Upper House in Hungary, the Főrendikus or House of Magnates (see Hungary).

MAGNES (c. 400 B.C.), Athenian writer of the Old Comedy, a native of the deme of Icaria in Attica. His death is alluded to by Aristophanes (Equites, 518–523, which was brought out in 424 B.C.), who states that in his old age Magnes had lost the popularity which he had formerly enjoyed. The few titles of his plays that remain, such as the Frogs, the Birds, the Gall-Flies, indicate that he anticipated Aristophanes in introducing grotesque costumes for the chorus.

See T. Kock, Comicorum Attorum fragmenta, i. (1880); G. H. Boden, Geschichte der hellenischen Diskhund, iii. pt. 2 (1840).

MAGNESIA, in ancient geography the name of two cities in Asia Minor and of a district in eastern Thessaly, lying between the Vale of Tempe and the Pagassaean Gulf.

(1) Magnesia ad Maenodrum, a city of Ionia, situated on a small stream flowing into the Maeander, 15 Roman miles from Miletus and rather less from Ephesus. According to tradition, reinforced by the similarity of names, it was founded by colonists from the Thessalian tribe of the Magnetes, with whom were associated, according to Strabo, some Cretan settlers (Magnesia retained a connexion with Crete, as inscriptions found there attest). It was thus not properly an Ionian city, and for this reason, apparently, was not included in the Ionian league, though superior in wealth and prosperity to most of the members except Ephesus and Miletus. It was destroyed by the Cimmerii in their irruption into Asia Minor, but was soon after rebuilt, and gradually recovered its former prosperity. It was one of the towns of the League of Arta, and by Artaxerxes to Themistocles for support in his exile, and there the latter ended his days. His statue stood in its market-place. Thibron, the Spartan, persuaded the Magnesians to leave their indefensible and mutinous city in 399 B.C. and build afresh at Leucoprys, an hour distant, noted for its temple of Artemis Leucopryne, which, according to Strabo, surpassed that at Ephesus in the beauty of its architecture, though inferior in size and wealth. Its ruins were excavated by Dr K. Humann for the Constantinople Museum in 1801–1803; but most of the frize of the temple of Artemis Leucopryne, representing an Amazon battle, had already been carried off by Texier (1843) to the Louvre. It was an octostyle, pseudo-dipteral temple of highly ornate Ionic order, built on older foundations by Hermogenes of Alabanda at the end of the 3rd century B.C. The platform has been greatly overgrown since the excavation, but many bases, capitals, and other architectural members are visible. In front of the west façade stood a great altar. An immense peribolus wall is still standing (30 ft. high), but its Doric colonnade has vanished. The railway runs right through the precinct, and much of Magnesia has gone into its bridges and embankments. South and west of the temple are many other remains of the Roman city, including a fairly perfect theatre excavated by Hiller von Gärtringen, and the shell of a large gymnasium. Part of the Agora was laid open to Humann, but his trenches have fallen in. The site is so unhealthy that even the Circassians who settled there twenty years ago have almost all died off or emigrated. Magnesia continued under the kings of Pergamum to be one of the most flourishing cities in this part of Asia; it resisted Mithradates in 87 B.C., and was rewarded with civic freedom by Sulla; but it appears to have greatly declined under the Roman empire, and its name disappears from history, though on coins of the time of Gordian it still claimed to be the seventh city of Asia.

See K. Humann, Magnesia am Mæander (1904).

(2) Magnesia ad Sipylum (mod. Manisa, q.v.), a city of Lydia about 40 m. N.E. of Smyrna on the river Hermus at the foot of Mt Sipylus. No mention of the town is found till 190 B.C., when Antiochus the Great was defeated under its walls by the Roman consul L. Scipio Asiacus. It became a city of importance under the Roman dominion and, though nearly destroyed by an earthquake in the reign of Tiberius, was restored by that emperor and flourished through the Roman empire. It was one of the few towns in this part of Asia Minor which remained prosperous under the Turkish rule. The most famous relic of antiquity is the "Niobe of Sipylus" (Suratu Tash) on the lowest slopes of the mountain about 4 m. east of the town. This is a colossal seated image cut in a niche of the rock, of "Hittite" origin, and perhaps that called by Pausanias the "very ancient statue of the Mother of the Gods," carved by Brotes, son of Tantalus, and sung by Homer. Near it lie many remains of a primitive city, and about half a mile east is the rock-seat conjecturally identified with Pausanias' "Throne of Pelops." There are also hot springs and a sacred grotto of Apollo. The whole site seems to be that of the early "Tantalus" city.

(D. G. H.)

MAGNESITE, a mineral consisting of magnesium carbonate, MgCO₃, and belonging to the calcite group of rhombohedral carbonates. It is rarely found in crystals or crystalline masses, being usually compact or earthy and intermixed with more or less hydrous magnesium silicate (meerschaum). The compact material has the appearance of unglazed porcelain, and the earthy that of chalk. In colour it is usually dead white, sometimes yellowish. The hardness of the crystallized mineral is 4; sp. gr. 3.1. The name magnesite as originally applied by J. C. Delamétherie in 1797 included several minerals containing magnesium, and at the present day it is used by French writers for meerschaum. The mineral has also been called bauderisite from the locality Bauderis near Ivrea in Piedmont. Breunnerite is a ferriferous variety.

Magnesite is a product of alteration of magnesium silicates, and occurs as veins and patches in serpentine, talc-schist or dolomite. It has an extensile cleavage, and is the chief constituent of the island Arboelega, near Salem in Madras, and in California, U.S.A. It is principally used for the manufacture of highly refractory firebricks for lining steel furnaces and electric furnaces; also for making plaster, tiles and artificial stone; for the preparation of magnesium salts (Epsom salts, &c.); for whitening paper-pulp and wool; and as a paint.

MAGNESIUM [symbol Mg, atomic weight 24.32 (O = 16)], a metallic chemical element. The sulphate of "Epsom salts" (q.v.) was isolated in 1695 by N. Grew, while in 1707 M. B. Valentin prepared magnesium alka from the mother liquors obtained in the manufacture of nitre. Magnesia was confounded with lime until 1755, when J. Black showed that the two substances were entirely different; and in 1808 Davy pointed out that it was the oxide of a metal, which, however, he was not able to isolate. Magnesium is found widely distributed in nature, chiefly in the forms of silicate, carbonate and chloride, and occurring in the minerals olivine, hornblende, talc, asbestos, meerschaum, augite, dolomite, magnesite, carnallite, kieserite and kainite. The metal was prepared in 1816 by G. A. W. Biedermann, and in 1825 by A. H. Becquerel, by the electrolysis of a solution of magnesium chloride. It is obtained by reducing magnesium oxide with carbon, or magnesium fluoride with aluminium. The metal is first prepared in the form of coarse plate, which is then reduced to a fine powder by the electro-chemical method. It is used in the manufacture of magnesium bronze, which is employed in the production of magnesium salts (Epsom salts, &c.), as a flux in wrought iron manufacture, in the manufacture of magnesium alloys, and in various other processes.

Magnesium is used in the manufacture of magnesium oxide, which is employed in the production of magnesium salts (Epsom salts, &c.), as a flux in wrought iron manufacture, in the manufacture of magnesium alloys, and in various other processes.

Moissan found that the oxide resisted reduction by carbon in the electric furnace, so that electrolysis of a fusible salt of the metal must be resorted to. Bunsen, in 1852, electrolysed fused magnesium chloride in a porcelain crucible. In later processes, carnallite (a
MAGNESIUM

natural double chloride of magnesiu and potassium) has commonly, after careful dehydration, been substituted for the single chloride. Gaetzel's process, which was at one time employed, consisted in electrolysising the chloride in a metal crucible heated externally, the crucible being placed in a tube within a large one which was filled with a bath of molten chloride and heated by the current of electricity passed through it. The deposited chloride is removed from the crucible by being heated upon its inner surface. W. Borchers also used an externally heated metal vessel as the cathode; it is provided with a supporting collar or flange a little below the top, so that the upper part of the vessel may be surrounded by a mantle of hot air to ensure the instant evaporation of the water thrown off when the metal is heated to redness in a current of air. The solution is evaporated, and the residue heated strongly, when water and ammonium chloride are expelled, and magnesium carbonate, MgCO₃, which readily forms double salts with the alkaline chlorides. A strong solution of the chloride made into a thick paste with calcined magnesia sets in a few hours to a hard, stone-like mass, which contains an oxygenate of magnesium, Mg₂O₂Cl₂, forms a varnish, and when heated to redness in a current of air evolves a mixture of hydrochloric acid and chlorine and leaves a residue of magnesia, which is employed in the Weldon-Pechiney and Mond processes for the production of magnesium metal.

Magnesium Carbonate, MgCO₃.—The normal salt is found native as the mineral magnesite, and in combination with calcium carbonate as dolomite, whilst hydromagnesite is a basic carbonate. It is not possible to regard it as a base nor as precipitating magnesium salts with sodium carbonate. C. Magnesium carbonate is prepared by mixing the action of calcium carbonate on magnesium chloride. A salt MgCO₃·3H₂O or Mg[(OH)(Cl)]·2H₂O may be prepared from the reaction MgO with carbon dioxide, and then reducing the precipitate (W. A. Davidson, Journ. Chem. Soc, 1875, p. 788). The carbonate is not easily soluble in dilute acids, but is readily soluble in water containing carbon dioxide. Magnesia alba, a white bulky precipitate obtained from adding sodium carbonate to a solution of magnesium chloride, is rapidly decomposed with carbon dioxide, and the precipitate of magnesium carbonate is then heated to 100°C., to which point the dilute carbonate will not decompose. This form of magnesium carbonate is marketed as a white and amorphous powder, readily soluble in carbon dioxide, and is used in photography. It is decomposed by hydrogen chloride gas or water to form the oxide MgO if magnesium chloride is evaporated with strong heat.

Magnesium Phosphates.—By adding phosphoric acid to magnesium hydroxide, a precipitate is formed, and allowing the mixture to stand, bentonite needles of MgHPO₄·7H₂O are deposited. The normal phosphate, MgHPO₄·5H₂O, is found in some guano, and as the mineral wagnerite. It may be prepared by adding normal sodium phosphate to a magnesium salt, and boiling the precipitate with a solution of calcium carbonate, and the precipitate with a solution of magnesium carbonate. In a manner similar, it is a white amorphous powder, readily soluble in acids.

Magnesium ammonium phosphate, MgNH₄PO₄·6H₂O, is found as the mineral wagnerite and in some guano; it occurs also in urinary calculi and is prepared in a manner similar to the magnesium carbonate. The magnesium salt is formed by heating sodium magnesium phosphate to form the per thermal ammonium phosphate, MgPO₄. Magnesium carbonate, MgCO₃, is a colourless, deliquescent, crystalline solid obtained by dissolving magnesium carbonate in an acid, and concentrating the solution. The product of magnesium pyrophosphate, Mg₃P₂O₇, Mg₃O₄, is obtained as a greenish-yellow amorphous mass by passing a current of nitrogen or ammonia over heated magnesia (F. Briegleb and A. Geuther, Ann., 1862, 123, p. 228; also W. Eitel, Ann., 1862, 124, p. 228; and L. A. Strecker, Ann., 1862, 125, p. 228). In dry air it becomes inspissating, forming a gas. Water decomposes it with liberation of ammonia and formation of magnesium hydroxide. The chlorides of nickel, cobalt, chromium, iron, and manganese are obtained in a manner similar to magnesium carbonate, whilst the chlorides of copper and platinum are reduced to the metals (A. Smits, Rec. Trav. Chin. 1861, 15, p. 135). Magnesium sulphide, MgS₂, may be obtained, mixed with some unaltered metal and some metal which was due to the melting of magnesium hydroxide, to form magnesium sulphur. It slowly decomposes in moist air. Magnesium sulphide, MgS₂, occurs with (H₂SO₄) as Kieserite. A hydrate is also known. The salt may be obtained from Kieserite; formerly it was prepared by treating magnesite or dolomite with sulphuric acid.

Organic Compounds.—By heating magnesium filings with methyl and ethyl iodides A. Cahours (Ann., 1860, 58, p. 59) obtained methyl magnesium, Mg(CH₃)₂, and magnesium ethyl, Mg(C₂H₅)₂, as colourless, slightly inflammable liquids, which are spontaneously inflammable and are readily decomposed by water. The compounds formed by the action of magnesium on alkyl iodides are of great importance in synthetic organic chemistry since V. Grignard (Comptes Rendus, 1902) defined the Grignard reagent (Organic Compounds) as a mixture of magnesium and alkyl, or aryl, halides, together in presence of anhydrous ether at ordinary temperatures (with the appearance of brisk boiling) to form complex compounds, which are organic in type (Grignard, A. 1902, 32, p. 327; Grignard, A. 1903, 34, p. 327). W. V. Deinard, who, in 1896, considered that they contain two molecules of ether. In preparing the Grignard reagent the commmencement of the reaction is accelerated by the presence of iodine. W. Tschemlczewski (Ber., 1904, 37, p. 4534) considered that the ether may be replaced by benzene containing a small quantity of ether or anisole, or a few drops of a tertiary amine. With unsaturated alkyl halides the products are only slightly soluble in ether, and two molecules of the alkyl compound are brought into
the reaction. They are very unstable, and do not react in the normal manner. (V. Grignard and L. Tissier, Comptes rendus, 1901, 132, p. 559.)

The products formed by the action of the Grignard reagent with the various forms of organic compounds are usually thrown out of solution in the form of crystalline precipitates or as thick oils, and are then decomposed by ice-cold dilute sulphuric or acetic acids, the magnesium being removed as a basic halide salt.

A double form of primary and secondary alcohols see ALDEHYDES and KETONES. Formaldehyde behaves abnormally with magnesium benzyl bromide (M. Tiffeneau, Comptes rendus, 1903, 137, p. 573), forming ortho-tolylcarbinol, CH₂C₆H₅-CH₂OH, and not benzylcarbinol, C₆H₅CH₂-CH₂OH (cf. the reaction for formaldehyde on phenols: O. Manasse, Ber. 1894, 27, p. 2904). Acid esters yield carbimols, many of which are unstable and readily pass over into unsaturated compounds, especially when warmed with acetic acid. The esters with the formula R-CONH-R' are converted into anhydride: R-CO-R' → R-CO-R + H₂O. Acid amides also react to form ketones (C. Béls, ibid., 1903, 137, 573): R-CO-NH₂ → R-COOMgX → R-CO-R + MgO.

A perfect yield is obtained with the nitrogen being eliminated as ammonia), the best results being given by the aromatic nitriles (E. Blaise, ibid., 1901, 133, p. 1217): R-CN → R'-C=N + MgO + R'-CO-R + CO₂. The amides also react to form ketones, and on heating: R-CN → R'-C=N + MgO + R'-CO-R + CO₂.

The yield increases with the complexity of the organic residue of the acid being used. On warming a current stream of carbon dioxide over the reagent, the gas is absorbed and the resulting compound, when decomposed by dilute acids, yields an organic acid, and similarly with carbon oxysulphide a thio-acid is obtained: R-Mgosx + COS → R-COS + MgO + CO₂.

A Klages (Ber. 1902, 35, p. 2633 et seq.), has shown that if one uses an excess of magnesium and of an alkyl halide with a ketone, an ethylene derivative is formed. The reaction appears to be perfectly general unless the ketone contains two ortho-substituting groups. Organic-metallic compounds can also be prepared, for example SnBr₄ + 4MgBr₂C₆H₅ → 4MgBr₂ + SnC₆H₅Br₄.

For a summary see A. McKenzie, B. A. Rep. 1907.

Detection. The magnesium salts may be detected by the white precipitate (forming magnesium sulfa double salt in the presence of ammonia and ammonium chloride) to their solutions. The same reaction is made use of in the quantitative determination of magnesium, the white precipitate of magnesium ammonium phosphate being converted into magnesium orthophosphate, and weight increases as such. The atomic weight of magnesium has been determined by many observers. J. Berzelius (Ann. chim. phys., 1820, 14, p. 375), by converting the oxide into the sulphate, obtained the value 12-02 for the equivalent. R. F. Marchand and F. Scherrer (Zeit. phys. Chem., 1890, 50, p. 358), by ignition of the carbonate, obtained the value 24-00 for the atomic weight, whilst C. Marignac, by converting the oxide into the sulphate, obtained the value 24-37. T. W. Richards and H. Parker (Zeit. phys. Chem., 1907, 13, p. 81) have obtained the value 24-365 (O = 16).

Medicine. These salts of magnesium may be regarded as the typical saline purgatives. Their acrid irritant action is dependent upon the minimum of irritation of the bowels, and is exercised by their abstraction from the blood of water, which passes into the bowel to act as a diluent of the salt. The stronger the solution administered, the greater is the quantity of water that passes into the bowel, a fact to be borne in mind when the salt is administered for the purpose of draining superfluous fluid from the system, as in dropsy. The oxide and carbonate of magnesium are also invaluable as antiseptics, since they form insoluble compounds with oxalic acid and salts of mercuric, arsenic, and copper. The result is to prevent the local corrosive action of the poison and to prevent absorption of the metals. As alkaloids are insoluble in alkaline solutions, the oxide and carbonate—especially the former—may be given in alkaloidal poisoning. The compounds of magnesium are not absorbed into the blood in any appreciable quantity, and therefore exert no remote actions upon other functions of the body. This is shown by the fact that a solution of a magnesium salt into a vein is rapid poisoning. Hence it is of the utmost importance to avoid the use of salts of this metal whenever it is necessary—as in diabetic coma—to increase the alkalinity of the blood rapidly. The usual doses of the oxide and carbonate of magnesium are from half a dram to a dram.

MAGNETISM. The present article is a digest, mainly from an experimental standpoint, of the leading facts and principles of magnetic science. It is divided into the following sections:

1. General Phenomena.
2. Terminology and Elementary Principles.
5. Magnetization in Weak Fields.
7. Effects of Mechanical Stresses on Magnetization.
8. Effects of Temperature on Magnetism.
11. Feebly Susceptible Substances.
13. Historical and Chronological Notes.

Of these thirteen sections, the first contains a simple description of the more prominent phenomena, without mathematical symbols or numerical data. The second includes definitions of technical terms in common use, together with so much of the elementary theory as is necessary for understanding the experimental work described in subsequent portions of the article; a number of formulae and results are given for purposes of reference, but the mathematical reasoning by which they are obtained is not generally detailed, authorities being cited whenever the demonstrations are not likely to be found in ordinary textbooks. The subjects discussed in the remaining sections are indicated by their respective headings. (See also ELECTROMAGNETISM, TERRESTRIAL MAGNETISM, MAGNETO-OPTIC and UNITS.)

1. General Phenomena

Pieces of a certain highly esteemed iron ore, which consists mainly of the oxide Fe₂O₃, are sometimes found to possess the power of attracting small fragments of iron or steel. One endowed with this curious property was well known to the ancient Greeks and Romans, who, because it occurred plentifully in the district of Magnesia near the Aegean coast, gave it the name of magnes, or the Magnesian stone. In English-speaking countries the ore is commonly known as magnetite, and pieces which exhibit attraction as magnets; the cause to which the attractive property is attributed is called magnetism, a name also applied to the important branch of science which has been evolved from the study of phenomena associated with the magnet.

If a magnet is dipped into a mass of iron filings and withdrawn, filings cling to certain parts of the stone in moss-like tufts, other parts remaining bare. There are generally two regions where the tufts are thickest, and the attraction therefore greatest, and between them is a zone in which no attraction is evidenced. The regions of greatest attraction have received the name of poles, and the line joining them is called the axis of the magnet; the space around a magnet in which magnetic effects are exhibited is called the field of magnetic force, or the magnetic field.

Up to the end of the 15th century only two magnetic phenomena of importance, besides that of attraction, had been observed. Upon one of these is based the principle of the mariner's compass, which is said to have been known to the Chinese as early as 1100 B.C., though it was not introduced into Europe until more than 2000 years later; a magnet supported so that its axis is free to turn in a horizontal plane will come to rest with its poles pointing approximately north and south. The other phenomenon is mentioned by Greek and Roman writers of the 1st century: a piece of iron, when brought near a magnet, is either held near one, itself becomes "inductively" magnetized, and acquires the power of lifting iron. If the iron is soft and fairly pure, it loses its attractive property when removed from the neighbourhood of the magnet; if it is hard, some of the induced magnetism is permanently retained, and the piece becomes an artificial magnet. Steel is much more retentive of magnetism than any ordinary iron, and some form of steel is now always used for making artificial magnets. Magnetism may be imparted to a bar of hardened steel by stroking it several times from end to end.
MAGNETISM

[GENERAL PHENOMENA]

end, always in the same direction, with one of the poles of a magnet. Until 1820 all the artificial magnets in practical use derived their virtue, directly or indirectly, from the natural magnets found in the earth: it is now recognized that the source of all magnetism, not excepting that of the magnetic ore itself, is electricity, and it is usual to have direct recourse to electricity for producing magnetization, without the intermediary of the magnetic ore. A wire carrying an electric current is surrounded by a magnetic field, and if the wire is bent into the form of an elongated coil or spiral, a field having certain very useful qualities is generated in the interior. A bar of soft iron introduced into the coil is at once magnetized, the magnetism, however, disappearing almost completely as soon as the current ceases to flow. Such a combination constitutes an electromagnet, a valuable device by means of which a magnet can be instantly made and unmade at will. With suitable arrangements of iron and coil and a sufficiently strong current, the intensity of the temporary magnetization may be very high, and electromagnets capable of lifting weights of several tons are in daily use in engineering works (see ELECTROMAGNETISM).

If the bar inserted into the coil is of hardened steel instead of iron, the magnetism will be less intense, but a larger proportion of it will be retained after the current has been cut off. Steel magnets of great strength and of any convenient form may be prepared either in this manner or by treatment with an electromagnet; hence the natural magnet, or lodestone as it is commonly called, is no longer of any interest except as a scientific curiosity.

Some of the principal phenomena of magnetism may be demonstrated with very little apparatus; much may be done with a small bar-magnet, a pocket compass and a few ounces of iron filings. Steel articles, such as knitting or sewing needles and pieces of flat spring, may be readily magnetized by stroking them with the bar-magnet; after having produced magnetism in any number of other bodies, the magnet will have lost nothing of its own virtue. The compass needle is a little steel magnet balanced upon a pivot; one end of the needle, which always bears a distinguishing mark, points approximately, but not in general exactly, to the north, the vertical plane through the direction of the needle being termed the magnetic meridian.

The bar-magnet, if suspended horizontally in a paper stirrup by a thread of unspun silk, will also come to rest in the magnetic meridian with its marked end pointing northwards. The north-seeking end of a magnet is in English-speaking countries called the north pole and the other end the south pole; in France the names are interchanged. If one pole of the bar-magnet is brought near the compass, it will attract the opposite pole of the compass-needle; and the magnetic action will not be sensibly affected by the interposition between the bar and the compass of any substance whatever except iron or other magnetizable metal. The poles of a piece of magnetized steel may be at once distinguished if the two ends are successively presented to the compass; that end which attracts the south pole of the compass needle (and is therefore north) may be marked for convenient identification.

Similar magnetic poles are not merely indifferent to each other, but exhibit actual repulsion. This can be more easily shown if the compass is replaced by a magnetized knitting needle, supported horizontally by a thread. The north pole of the bar-magnet will repel the north pole of the suspended needle, and there will likewise be repulsion between the two south poles. Such experiments as these demonstrate the fundamental law that like poles repel each other; unlike poles attract. It follows that between two neighbouring magnets, the poles of which are regarded as centres of force, there must always be four forces in action. Denoting the two pairs of magnetic poles by N, S and N', S', there is attraction between N and S, and between S and S'; repulsion between N and N', and between S and S'. Hence it is not very easy to determine experimentally the law of magnetic force between poles. The difficulty was overcome by C. A. Coulomb, who by using very long and thin magnets, so arranged that the action of their distant poles was negligible, succeeded in establishing the law, which has since been confirmed by more accurate methods, that the force of attraction or repulsion exerted between two magnetic poles varies inversely as the square of the distance between them. Since the poles of different magnets differ in strength, it is important to agree upon a definite unit or standard of reference in terms of which the strength of a pole may be numerically specified. According to the recognized convention, the unit pole is that which acts upon an equal pole at unit distance with unit force: a north pole is reckoned as positive (+) and a south pole as negative (−). Other conditions remaining unchanged, the force between two poles is proportional to the product of their strengths; it is repulsive or attractive according as the signs of the poles are like or unlike.

If a wire of soft iron is substituted for the suspended magnetic needle, either pole of the bar-magnet will attract either end of the wire indifferently. The wire will in fact become temporarily magnetized by induction, that end of it which is nearest to the pole of the magnet acquiring opposite polarity, and behaving as if it were the pole of a permanent magnet. Even a permanent magnet is susceptible of induction, its polarity becoming thereby strengthened, weakened, or possibly reversed. If one pole of a strong magnet is presented to the like pole of a weaker one, there will be repulsion so long as the two are separated by a certain minimum distance. At shorter distances the magnetism induced in the weaker magnet will be stronger than its permanent magnetism, and there will be attraction; two magnets with their like poles in actual contact will always cling together unless the like poles are of exactly equal strength. Induction is an effect of the field of force associated with a magnet. Magnetic force has not merely the property of acting upon magnetic poles, it has the additional property of producing a phenomenon known as magnetic induction, or magnetic flux, a physical condition which is of the nature of a flow continuously circulating through the magnet and the space outside it. Inside the magnet the course of the flow is from the south pole to the north pole; hence it diverges through the surrounding space, and again converging, re-enters the magnet at the south pole. When the magnetic induction flows through a piece of iron or other magnetizable substance placed near the magnet, a south pole is developed where the flux enters and a north pole where it leaves the substance. Outside the magnet the direction of the magnetic induction is generally the same as that of the magnetic force. A map indicating the direction of the force in different parts of the field due to a magnet may be constructed in a very simple manner. A sheet of cardboard is placed above the magnet, and some iron filings are sifted thinly and evenly over the surface; if the cardboard is gently tapped, the filings will arrange themselves in a series of curves, as shown in fig. 1.

This experiment suggested to Faraday the conception of lines of force, of which the curves formed by the filings afford a rough indication; Faraday's lines are however not confined to the plane of the cardboard, but occur in the whole of the space around the magnet. A line of force may be defined as an imaginary line so drawn that its direction at every point of its course coincides with the direction of the magnetic force at that point. Through any point in the field one such line can be drawn, but not more than one, for the force obviously cannot have more than one direction; the lines therefore never intersect. A line of force is regarded as proceeding from the north pole towards the south pole of the magnet, its direction being that in which an isolated north pole would be urged along
MAGNETISM

it. A south pole would be urged oppositely to the conventional "direction" of the line; hence it follows that a very small magnetic needle, if placed in the field, would tend to set itself along or tangentially to the line of force passing through its centre, as may be approximately verified if the compass be placed among the filings on the cardboard. In the internal field of a long coil of wire carrying an electric current, the lines of force are, except near the ends, parallel to the axis of the coil, and it is chiefly for this reason that the field due to a coil is particularly well adapted for inductively magnetizing iron and steel. The older operation of magnetizing a steel bar by drawing a magnetic pole along it merely consists in exposing successive portions of the bar to the action of the strong field near the pole.

Faraday's lines not only show the direction of the magnetic force, but also serve to indicate its magnitude or strength in different parts of the field. Where the lines are crowded together, as in the neighbourhood of the poles, the force is greater (or the field is stronger) than where they are more widely separated; hence the strength of a field at any point can be accurately specified by reference to the concentration of the lines. The lines presented to the eye by the scattered filings are too vague and ill-defined to give a satisfactory indication of the field-strength (see Faraday, Experimental Researches, § 3237) though they show its direction clearly enough. It is however easy to demonstrate by means of the compass that the force is much greater in some parts of the field than in others. Lay the compass upon the cardboard, and observe the rate at which its needle vibrates after being displaced from its position of equilibrium; this will vary greatly in different regions. When the compass is far from the magnet, the vibrations will be comparatively slow; when it is near a pole, they will be exceedingly rapid, the frequency of the vibrations varying as the square root of the magnetic force at the spot.

At a point where the intensity of a magnetic field at a given place, just as the inclination of the earth at different parts is deduced from observations of the rate at which a pendulum of known length vibrates.

It is the non-uniformity of the field surrounding a magnet that the apparent attraction between a magnet and a magnetizable body such as iron is ultimately due. This was pointed out by W. Thomson (afterwards Lord Kelvin) in 1847, as the result of a mathematical investigation undertaken to explain Faraday's experimental observations. If the inductively magnetized body lies in a part of the field which happens to be uniform there will be no resulting force tending to move the body, and it will not be "attracted." If however there is a small variation of the force in the space occupied by the body, it can be shown that the body will be urged, not necessarily towards a magnetic pole, but towards places of stronger magnetic force. It will not in general move along a line of force, as would an isolated pole, but will follow the direction in which the magnetic force increases most rapidly, and in so doing it may cross the lines of force obliquely or even at right angles.

If a magnetized needle were supported so that it could move freely about its centre of gravity it would not generally settle with its axis in a horizontal position, but would come to rest with its north-seeking pole either higher or lower than its centre. For the practical observation of this phenomenon it is usual to employ a needle which can turn freely in the plane of the magnetic meridian upon a horizontal axis passing through the centre of gravity of the needle. The angle which the magnetic axis makes with the plane of the horizon is called the inclination or dip. Along an irregular line encircling the earth in the neighbourhood of the geographical equator the needle takes up a horizontal position, and the dip is zero. At places north of this line, where the north magnetic pole lies above the earth, the needle points downwards, and the dip being 90° South of the magnetic equator the south end of the needle is always inclined downwards, and there is a spot within the Antarctic Circle (148° E. long., 74° S. lat.) where the needle again stands vertically, but with its north end directed upwards. All these observations may be accounted for by the fact first recognized by W. Gilbert in 1600, that the earth itself is a great magnet, having its poles at the two places where the dipping needle is vertical. To be consistent with the terminology adopted in Britain, it is necessary to regard the pole which is geographically north as being the south pole of the terrestrial magnet, and that which is geographically south as the north pole; in practice however the names assigned to the terrestrial magnetic poles correspond with their geographical situations. Within a limited space, such as that contained in a room, the field due to the earth's magnetism is sensibly uniform, the lines of force being parallel straight lines inclined to the horizon at the angle of dip, which at Greenwich in 1910 was about 67°. It is by the horizontal component of the earth's total force that the compass-needle is directed.

The magnets hitherto considered have been assumed to have two poles, the one north and the other south. It is possible that there may be more than two. If, for example, a knitting needle is stroked with the south pole of a magnet, the strokes being directed from the middle of the needle towards the two extremities alternately, the needle will acquire a north pole at each end and a south pole in the middle. By suitably modifying the manipulation a further number of consequent poles, as they are called, may be developed. It is also possible that a magnet may have no poles at all. Let a magnetic pole be drawn several times around a uniform steel ring, so that every part of the ring may be successively subjected to the magnetic force. If the operation has been skillfully performed the ring will have no poles and will not attract iron filings. Yet it will be magnetized; for if it is cut through and the cut ends are drawn apart in every rc, will exhibit an indefinite polarity. Again, if a steel wire through which an electric current has been passed will be magnetized, but so long as it is free from stress it will give no evidence of magnetization; if, however, the wire is twisted, poles will be developed at the two ends, for reasons which will be explained later. A wire or rod in this condition is said to be "circularly magnetized"; it may be regarded as consisting of an indefinite number of elementary ring-magnets, having their axes coincident with the axis of the wire and their planes at right angles to it. But no magnet can have a single pole; if there is one, there must also be at least a second, of the opposite sign and of exactly equal strength. Let a magnetized knitting needle, having north and south poles at the two ends respectively, be broken in the middle; each half will be found to possess a north and a south pole, the appropriate supplementary poles appearing at the broken ends. One of the fragments may again be broken, and again two bipolar magnets will be produced; and the operation may be repeated, at least in imagination, till we arrive at molecular magnitudes and can go no farther. This experiment proves that the condition of magnetization is not confined to those parts where polar phenomena are exhibited, but exists throughout the whole body of the magnet; it also suggests the idea of molecular magnetism, upon which the accepted theory of magnetization is based. According to this theory the molecules of any magnetizable substance are little permanent magnets the axes of which are, under ordinary conditions, disposed in all possible directions indifferently. The process of magnetization consists in turning round the molecules by the application of magnetic force, so that their north poles may all point more or less approximately in the direction of the force; thus the body as a whole becomes a magnet which is merely the resultant of an immense number of molecular magnets.

In every magnet the strength of the south pole is exactly equal to that of the north pole, the action of the same magnetic force upon the two poles being equal and oppositely directed. This may be shown by means of the uniform field of force due to the earth's magnetism. A magnet attached to a cork and
Magnetism

Magnetism—The liquid other substances Optics. In weight Magnetic the direction that was all magnetic resultant points. Magnetic phenomena, and in 1903 the interesting discovery was made by F. Heusler that an alloy consisting of copper, aluminium and manganese (Heusler's alloy), possesses magnetic qualities comparable with those of iron. Practically the metals iron, nickel and cobalt, and some of their alloys and compounds constitute a class by themselves and are called ferromagnetic substances. But it was discovered by Parady in 1845 that all substances, including even gases, are either attracted or repelled by a sufficiently powerful magnetic pole. This powerful magnetic pole, being a point of highest magnetic density, is a magnetic pole. Between the ferromagnetics and the paramagnetics there is an enormous gap. The maximum magnetic susceptibility of iron is half a million times greater than that of liquid oxygen, one of the strongest paramagnetic substances known. Bismuth, the strongest of the diamagnetics, has a negative susceptibility which is numerically 20 times less than that of liquid oxygen.

Many of the physical properties of a metal are affected by magnetization. The dimensions of a piece of iron, for example, its elasticity, its thermo-electric power and its electric conductivity are all changed under the influence of magnetism. On the other hand, the magnetic properties of a substance are affected by such causes as mechanical stress and changes of temperature. An account of some of these effects will be found in another section.

2. Terminology and Elementary Principles

In what follows the C.G.S. electromagnetic system of units will be generally adopted, and, unless otherwise stated, magnetic substances will be assumed to be isotropic, or to have the same physical properties in all directions.

Vectors.—Physical quantities such as magnetic force, magnetic induction and magnetization, which have direction as well as magnitude, are termed vectors; they are compounded and resolved in the same manner as mechanical force, which is itself a vector. When the direction of any vector quantity denoted by a symbol is to be attended to, it is usual to employ for the symbol either a block letter, as H, I, B, or a German capital, as S, M, B. Magnetic Polarisation and Magnetic Axis.—A unit magnetic pole is that which is capable of producing at a distance of one centimetre with a force of one dyne. A pole which points north is reckoned positive, one which points south negative. The action between any two magnetic poles is mutual. If m₁ and m₂ are the strengths of two poles, d the distance between them expressed in centimetres, and f the force in dynes,

\[ f = \frac{m_1 m_2}{d^2} \]  

The force is one of attraction or repulsion, according as the sign of the product \( m_1 m_2 \) is positive or negative. The poles at the ends of an infinitely thin uniform magnet, or magnetic filament, would act as definite centres of force. An actual magnet may generally be regarded as a bundle of magnetic filaments, and those portions of its axis of the magnet where the filaments terminate, and so-called "free magnetism" appears, may be conveniently called poles or polar regions. A more precise definition is the following: When the magnet is placed in a uniform field, the parallel forces acting on the positive poles of the constituent filaments, whether the filaments terminate outside the magnet or inside, have a resultant, equal to the sum of the forces and parallel to their direction, acting at a certain point \( N \). The point \( N \), which is the centre of the parallel forces, is called the north or positive pole of the magnet. Similarly, the resultant of the forces acting on the negative poles of the filaments have a resultant at another point \( S \), which is called the south or negative pole. The opposite and parallel forces acting on the poles are always equal, a fact which is sometimes expressed by the term 'magnet at a tangent'.

The line joining the two poles is called the axis of the magnet.

Magnetic Field.—Any space at every point of which there is a finite magnetic force is called a field of magnetic force, or a magnetic field. The strength or intensity of a magnetic field at any point is measured by the force in dynes which a unit pole will experience when placed at that point, the direction of the field being the direction in which a positive pole is urged. The field-strength at any point is also called the magnetic force at that point; it is denoted by \( H \), or, when it is desired to draw attention to the fact that it is equal to a certain electric current, \( H = i \). Magnetic force is sometimes, and perhaps more suitably, termed magnetic intensity; it corresponds to the intensity of gravity \( g \) in the theory of heavy bodies (see Maxwell, Electricity and Magnetism, § 12 and § 68, footnote). A line of force is a line drawn through a magnetic field in the direction of the force at each point through which it passes. A uniform magnetic field is one in which \( H \) has everywhere the same value and direction, and the lines of force are, therefore, straight and parallel. A magnetic field is generally due to either a conductor carrying an electric current or to the poles of a magnet. The magnetic field due to a long straight wire in which the current is uniform is the same at every point at right angles to the plane passing through it and through the wire; its strength at any point distant \( r \) centimetres from the wire is

\[ H = \frac{2i}{\pi r} \]

\( i \) being the current in C.G.S. units. The lines of force are evidently circles concentric with the wire and at right angles to it; their direction is related to that of the current in the same manner as the direction of a corkscrew is related to its thrust. The field at the centre of a current-carrying conductor of radius \( r \) through which current is passing is

\[ H = \frac{4\pi i}{r} \]

In the middle portion of the coil the strength of the field is very nearly uniform, but towards the end it diminishes, and at the ends is reduced to one-half. The direction of the force is parallel to the axis of the coil, and related to the direction of the current as the direction of a corkscrew is related to its thrust. The coil has the form of a ring of mean radius \( r \), the length will be \( 2\pi r \), and the field inside the coil may be expressed as

\[ H = \frac{2\pi i}{r} \]

The uniformity of the field is not in this case disturbed by the influence of ends, but its strength at any point varies inversely as the distance from the axis of the ring. When therefore sensible uniformity is desired, the radius of the ring should be large in relation to that of the convolutions, or the ring should have the form of a short cylinder with a corkscrew to it. If the coil has the form of a ring of mean radius \( r \), the length will be \( 2\pi r \), and the field inside the coil may be expressed as

\[ H = \frac{2\pi i}{r} \]

3. Clerk Maxwell employed the C.G.S. unit of current = 10 amperes.
an angle \( \alpha \) with the normal, the normal component of the magnetization, \( I \cos \alpha \), is called the surface density of the magnetism, and is generally denoted by \( \sigma \).

**Potential and Magnetic Force.**—The magnetic potential at any point in a magnetic field is the work which would be done against the magnetic forces in bringing a unit pole to that point from the boundary of the field. The line through the given point along which the potential decreases most rapidly is the direction of the resultant magnetic force, and the rate of decrease of the potential in any direction is equal to the component of the force in that direction. If \( V \) denote the potential, \( F \) the resultant force, \( X, Y, Z \), its components parallel to the co-ordinate axes and \( n \) the line along which the force is directed, then

\[
\frac{\delta V}{\delta x} = F_x, \quad \frac{\delta V}{\delta y} = F_y, \quad \frac{\delta V}{\delta z} = F_z.
\]

Surfaces for which the potential is constant are called equipotential surfaces. The resultant magnetic force at every point of such a surface is in the direction of the normal (\( n \)) to the surface; every line of force therefore cuts the equipotential surfaces at right angles. The potential due to a single pole of strength \( m \) at the distance \( r \) from the pole is

\[
V = \frac{m}{r},
\]

the equipotential surfaces being spheres of which the pole is the centre and the lines of force radii. The potential due to a thin magnet at a point whose distance from the two poles respectively is \( r \) and \( r' \) is

\[
V = \frac{m}{r} + \frac{m}{r'}.
\]

When \( V \) is constant, this equation represents an equipotential surface.

The equipotential surfaces are two series of ovoids surrounding the two poles respectively, and separated by a plane at zero potential passing perpendicularly through the middle of the axis. If \( r \) and \( r' \) make angles \( \theta \) and \( \theta' \) with the axis, it is easily shown that the equation to a line of force is

\[
\cos \theta - \cos \theta' = \text{constant}.
\]

At the point where a line of force intersects the perpendicular bisector of the axis \( r = r' = r_0 \), say, and \( \cos \theta - \cos \theta' \) obviously \( = 1/r_0, 1 \) being bisecting the magnet perpendicularly, \( \theta = \pi/2 \) therefore \( \cos \theta \equiv 0 \), and the point \( D \) is at an infinite distance. The magnitude of the force is in this case

\[
F = \frac{M}{r^2},
\]

and its direction is parallel to the axis of the magnet. Although the above formulae (10) and (15) are true only for an infinitely small magnet, they may be practically applied whenever the distance \( r \) is considerable compared with the length of the magnet.

**Couples and Forces between Magnets.**—If a small magnet of moment \( M \) is placed in the region of a fixed magnet \( M' \), a couple tending to turn the small magnet upon an axis at right angles to the magnet and to the force is

\[
\text{MM}' = (\sin \theta \cos \theta - \sin \phi \cos \phi) \cdot r^3.
\]

This vanishes if \( \sin \theta \cos \phi - \sin \phi \cos \theta = 0 \), i.e. if \( \tan \phi = \frac{1}{\tan \theta} \), \( SN' \) being then along a line of force, a result which explains the construction given above for finding the direction of the force \( F \) in (11). If the axis of \( SN' \) produced passes through the centre of \( SN' \), \( \theta = 0 \), and the couple becomes

\[
2M'M' \sin^2 \phi.
\]

(19) tend to diminish \( \phi \); this is called the "end on" position. If the centre of \( SN' \) is on the perpendicular bisector of \( SN', \theta = \pi/2\), and the couple will be

\[
\text{MM}' \cos \phi.
\]

(20) tend to increase \( \phi \); this is the "broadside on" position. These two positions are sometimes called the first and second (or A and B) principal positions of Gauss. The components \( X, Y, Z \), parallel and perpendicular to \( r \), of the force between the two magnets \( SN' \) are

\[
X = 3M'M' \sin \theta \sin \phi \cos \cos \phi \cdot r^3,
\]

\[
Y = 3M'M' \sin \phi \cos \phi \cdot r^3
\]

It will be seen that, whereas the couple varies inversely as the cube of the distance, the force is directly inversely as the fourth power

\[
\text{Distributions of Magnetism.}—A \text{magnet may be regarded as consisting of an infinite number of elementary magnets, each having a pair of poles and a definite magnetic moment. If a series of such elements, all equally and longitudinally magnetized, were placed end to end with their unlike poles in contact, the external action of the filament thus formed would be reduced to that of the two extreme poles. The same would be the case if the magnetization of the filament varied inversely as the area of its cross-section (or as the volume of elements, such as a bar magnet, and the magnetism is said to be distributed lamellarly. A thin sheet of magnetic material magnetized normally to its surface in such a manner that the magnetization at any place is inversely proportional to the thickness \( k \) of the sheet at that place is called a magnetic shell; the constant product \( AI \) is the strength of the shell elements, all equally and longitudinally magnetized,} \]

\[
\text{It can be shown that uniform magnetization is possible only when the form of the body is ellipsoidal. (Maxwell, Electricity and Magnetism, II., § 437). The cases of greatest practical importance are those of a sphere (which is an ellipsoid with three equal axes) and an ovoid or prolate ellipsoid of revolution. The potential due to a uniformly magnetized sphere of radius \( a \) for an external point at a distance \( r \) from the centre is}
\]

\[
V = \frac{4\pi a I \cos \theta}{r},
\]

\( \theta \) being the inclination of \( r \) to the magnetic axis. Since \( \xi \) is the moment of the sphere \( (V = \text{volume} \times \text{magnetization}) \), it appears from (10) that the magnetized sphere produces the same external effect as a very small magnet of equal moment placed at its centre and magnetized in the same direction; the resultant force therefore is the same as in (14). The force in the interior is uniform, opposite
to the direction of magnetization, and equal to $\pi I$. When it is
desired to have a uniform magnet with definitely situated poles, it
usual to employ one having the form of an ovoid, or elongated
ellipsoid of revolution, instead of a cylindrical or rectangular bar.
If, however, the pole-spaces are rectangular, and the length of
the major and minor axes are $2a$ and $2e$, the poles are situated at
a distance equal to $a$ from the centre, and the magnet will behave
externally like a simple solenoid of length $2a$. The internal force $F$
acting upon the magnet is a function of the distance $d$ and equal to
$N$, where $N$ is a coefficient depending only on the ratio of the axes.
The moment $= 2\pi a^2 = -\pi a^2 FN$.

The distribution of magnetism and the poles in magnetic or
dia- or rectangular bars cannot be specified by any general statement,
though approximate determinations may be obtained experimentally in individual cases. According to F. W. G. Kohlrausch the distance between the poles of the same strength, in terms of the length of the bar, is sensibly equal to
fifths of the length of the bar. This statement, however, is only approximately correct, the distance between the poles depending upon the intensity of the magnetiza-
tion, the greater $B$, the closer is the situation. A special point
more nearly will the poles approach the end of the bar, and the more
nearly uniform will be the magnetization. For most practical purposes a knowledge of the exact position of the poles is of no im-
portance; the magnetic moment, and therefore the mean magnetiza-
tion, may be determined with accurate

**Magnetic Induction or Magnetic Flux.**—When magnetic force acts
on any medium, whether magnetic, diamagnetic or neutral, it pro-
duces a reaction known as the nature of a flux or flow called
magnetic induction (Maxwell, loc. cit., §§ 448).

Magnetic induction like other fluxes such as electrical, thermal or fluid currents, is defined with reference to an area; it satisfies the same conditions of continuity as the earlier electric current, and in isotropic media it depends on the magnetic field and the area of the boundary of the extended
magnetic force. The magnitude of the flux produced by a given
magnetic force differs in different media. In a uniform magnetic
field of unit intensity formed in empty space the induction or magnetic
flux is equal to the area of the square centimetre normal to the direction
of the field is arbitrarily taken as the unit of induction. Hence if the
induction per square centimetre at any point is denoted by $B$, then
in empty space $B$ is numerically equal to $H$; moreover in isotropic media the induction is proportional to the permeability of the medium.

In the case of a straight uniformly magnetized bar the direction
of the magnetic force due to the poles of the magnet is from the north
to the south pole outside the magnet, and from the south to the north
inside. The magnetic flux per square centimetre at any point
$(B/H)$ is the same in all media. When the induction in the bar is
considered as the flux per square centimetre normal to the contour of
a small surface form a re-entrant tube bounded by lines of
induction; such a tube is called a tube of induction. The section
of a tube of induction may vary in different parts, but the total
induction along it is everywhere the same. The meaning has been assigned to the term "lines of induction." Sup-
pose the whole space in which induction exists to be divided up into
units tubes, such that the surface integral of the induction over any
contour of a tube is equal to unity, and along the contour of a tube let a line of induction be drawn. These axial lines constitute
the system of lines of induction which are so often referred to in the
specification of a field. Where the induction is high the lines will
be crowded together; if it is low they will be more widely separated.
The number per square centimetre crossing a normal section of
the line of induction may therefore be specified as $B$ lines per square centimetre. The direction of induction is also of course indicated by the
direction of the lines, which may be either contemporaneous or
in opposite manner. Lines of induction are frequently but inaccurately spoken of as lines of force.

If a piece of ferromagnetic metal, that has not become magnetized, but that is magnetized at any point is proportional not to $B$, but to $B-H$. The factor of proportionality will be $1-4\pi$, so that

$$l = (B-H)/4\pi,$$

$$B = H + 4\pi l.$$  

(24) 

Unless the path of the induction is entirely inside the metal, free
g macro poles are developed at those parts of the metal where induction enters and leaves, the poles being south at the entrance
and north at the exit of the flux. These free poles produce a magnetic
field, and it is the magnetic field which is described upon that, arising from other sources. The direction of the resultant magnetic
field is to determine, for no pole is produced by a closed circuit of two fields, the one being due to the poles, and the other to the external causes which would be operative in the absence of the magnetized metal. The
intensity (at any point) of the field due to the magnetization may be
denoted by $H$, that of the external field by $B$, and that of the re-
sultant field by $H$. In certain cases, for instance, in an iron ring
wound uniformly round with a coil of wire through which a current
is passing, the induction is entirely within the metal; there are, conse-
quence, no poles, and the ratio of the fluxes would constitute a poleless
magnet. Magnetization is usually regarded as the direct effect of the resultant magnetic force, which is therefore
often termed the magnetizing force.

In general the ratio $B/H$ is called the permeability of the medium in which the induction is taking place, and is denoted by $\mu$. The ratio $I/H$ is called the susceptibility of the
magnetized substance, and is denoted by $k$. Hence

$$B = \mu H,$$

$$\mu = \mu_{R} = \frac{1}{4\pi I},$$

and

$$k = \frac{\mu - 1}{\mu + 1}.$$  

(25) 

(26)

Since in empty space $B$ is taken as being numerically equal to $H$, it follows that the permeability of a vacuum is $1$. The permeability of most material substances differs very slightly from unity, being a little greater than 1 in paramagnetic and a little less in diamagnetic substances. In the case of the ferromagnetic
substances, on the other hand, the permeability is much greater,
and has generally a much higher value. Moreover, it is not constant, being an
apparently arbitrary function of $H$ or $B$; in the same specimen its value may, under different conditions, vary from less than 2 to
more than 1000. This is often referred to as the numerical relation of the magnetization to the magnetizing force.

From the equation $\kappa = (\mu - 1)/\mu$ it follows that the magnetic
susceptibility of a vacuum $(\mu = 1)$ is 0, that of a diamagnetic
substance, in which $\mu < 1$, is negative, and that of a paramagnetic
substance, in which $\mu > 1$, is positive. No substance has yet been discovered having a negative susceptibility sufficiently great to render the permeability $(= 1 + 4\pi \kappa)$
negligible.

**Magnetic Circuit.**—The circulation of magnetic induction or flux
through magnetic and non-magnetic substances, such as iron and
air, is in many respects analogous to that of an electric current
through good and bad conductors. Just as the lines of flow of an
electric current all unite at every section, so do all the lines of induction pass in closed curves through the magnet or magnetizing coil. The total magnetic induction or flux corresponds to the current of electricity (practically measured by the instrument of the ampere), but it is of different
nature, in that the intensity of the magnetic induction (number of amperes to the square centimetre of section) is not in general constant; there is no perfect insulator for magnetic induction, which will pass more or less freely through all known substances. Nevertheless, many important
problems relating to the distribution of magnetic induction may be
solved by methods similar to those employed for the solution of
related problems in the elementary theory of the magnetic circuit see ELECTRO-MAGNETISM.

**Hysteresis, Coercive Force, Retention.-** It is found that when
a piece of ferromagnetic metal, such as iron, is subjected to a magnetic
field, the material, as it were, "remembers" the direction of the field,
even when it is afterwards reduced to zero, the magnetization does not
entirely disappear. This residual magnetization is one of the principal
phenomena of hysteresis and is expressed by the term "coercive
force." A remanent magnetization is also developed by certain
poles of hysteresis is presented by the case of permanent magnets. If
a bar of hard steel is placed in a strong magnetic field, a certain
intensity of magnetization is induced in the bar; but when the
strength of the field is afterwards reduced to zero, the magnetization does not
entirely disappear but remains in the iron, and which may amount to considerably more than one-half, is called
the residual magnetization. The ratio of the residual magnetization
to its previous maximum value measures the retention, or

---

1 The principal theoretical investigations are summarized in
Mascart and Joubert’s Electricity and Magnetism, i. 391–398 and

4 See C. G. Lamb, loc. cit. p. 518.
**MAGNETISM**

In the middle part of a rod which has a length of 400 or 500 diameters the effect of the ends is insensible; but for many experiments the condition of the ends may be best secured by giving the metal the shape of a ring of uniform section, the magnetic field being produced by an electric coil through which the wire is wound round the ring. In such cases \( H_1 = 0 \) and \( H = H_0 \).

The residual magnetization \( I \), retained by a bar of ferromagnetic metal after it has been removed from the influence of an external field produces a demagnetizing force which is greater than the value of the field within the body is therefore impossible.

Demagnetization by Reversals.—In the course of an experiment it is often desired to eliminate the effects of previous magnetization, and, as far as possible, wipe out the magnetic history of a specimen. In order to attain this result it was formerly the practice to raise the metal to a bright red heat, and allow it to cool while carefully guarded from magnetic influence. This operation, besides being very troublesome, was open to the objection that it was almost sure to produce a material but uncertain change in the physical constitution of the metal, so that, in fact, the results of experiments made before and after the treatment were not comparable. Ewing introduced the method (Phil. Trans. clxvii, 439) of demagnetizing a specimen by subjecting it to a succession of magnetic forces which alternated in direction and gradually diminished in strength from a high value to zero. By means of a simple arrangement, which will be described farther on, this process can be carried out in a few seconds, and the metal can be brought as often as desired to a definite condition, which, if not quite identical with the virgin state, at least closely approximates to it.

**Forces acting on a Small Body in the Magnetic Field.**—If a small magnet of length \( d \) and pole-length \( m \) is brought into a magnetic field such that the values of the magnetic potential at the negative and positive poles respectively are \( V_1 \) and \( V_2 \), the work done upon the magnet, and therefore its potential energy, will be

\[
W = m(V_2 - V_1) = mdV
\]

which may be written

\[
W = \int_{V_1}^{V_2} m dV = mV^2 = -\int H dV = -vH_1dH_1
\]

where \( M \) is the moment of the magnet, \( v \) the volume, \( I \) the magnetization, and \( H_2 \) the magnetic force along \( dz \). The small magnet may be a sphere rigidly magnetized in the direction of \( H_2 \); if this is replaced by an isotropic sphere indeducitively magnetized by the field, then, for a displacement so small that the magnetic field of the sphere may be regarded as unchanged, we shall have

\[
dW = -vH_1dH_1 = -\frac{1}{2}vH_1^2dH_1;
\]

whence

\[
W = \frac{1}{2}vH_1^2B^2.
\]

The mechanical action force acting on the sphere in the direction of displacement \( x \) is

\[
F = \frac{dW}{dx} = \frac{1}{2}vH_1^2\frac{dH_1}{dx}
\]
If \( H_0 \) is constant, the force will be zero; if \( H_0 \) is variable, the sphere will tend to move in the direction in which \( H_0 \) varies most rapidly. The coefficient \( k/(1+4\pi) \) is positive for ferromagnetic and paramagnetic substances, which will therefore tend to move from weaker to stronger parts of the field; for all known diamagnetic substances it is negative, and these will tend to move from stronger to weaker parts. For small bodies other than spheres the coefficient will be different, but its sign will always be negative for diamagnetic substances and positive for other substances. Forces acting on any small body will be in the same directions as in the case of a sphere.\(^2\)

**Directing Couple acting on an Elongated Body.**—In a non-uniform field every volume-element of the body tends to move towards regions of greater or less force according as the substance is paramagnetic or diamagnetic, and the behaviour of the whole mass will be determined chiefly by the tendency of its constituent elements. For this reason a thin bar suspended at its centre of gravity between a pair of magnetic poles will, if paramagnetic, set itself along the line joining the poles, whereas if it is diamagnetic, the forces acting on any small part will be in the same directions as in the case of a sphere.\(^3\)

**Circular Magnetization.**—An electric current \( i \) flowing uniformly through a cylindrical wire whose radius is \( a \) produces inside the wire a magnetic field of which the lines of force are concentric circles around the axis of the wire. At a point whose distance from the axis of the wire is \( r \) the tangential magnetic force is:

\[
H = 2\pi i a^2 r
\]

where \( i \) is the current, \( a \) the radius of the wire, and \( r \) the distance from the axis.\(^4\)

**Magnetic Shielding.**—The action of a hollow magnetized shell on a point inside it is always opposed to that of the external magnetizing force,\(^5\) the resultant interior field being therefore weaker than the field outside. Hence any apparatus, such as a galvanometer, may be partially shielded from extraneous magnetic action by enclosing it in an iron case. If a hollow sphereof such an outer radius is \( R \) and the inner radius \( r \), where \( r < R \), is placed in a uniform field \( H_0 \), the resultant field inside will also be uniform and in the same direction as \( H_0 \), and its value will be approximately:

\[
H_i = \frac{H_0}{1 + \left(\frac{r}{R}\right)^2}
\]

For a cylinder placed with its axis at right angles to the lines of force,

\[
H_i = \frac{H_0}{1 + \left(\frac{r}{R}\right)^2}
\]

These expressions show that the thicker the screen and the greater its permeability \( \mu \), the more effectual will be the shielding action. Since \( \mu \) may be very infinite, complete shielding is possible.

**Magnet-Crystal Phenomenon.**—In anisotropic bodies, such as crystals, the direction of the magnetization does not in general coincide with that of the magnetic field. There may be, however, always throughout the body certain directions in which the field lines along which the magnetization and the force have the same direction. If each of these axes successively is placed parallel to the lines of force in a uniform field \( H \), we shall have:

\[
\mu s_x = \mu s_y = \mu s_z = H
\]

the susceptibilities \( \mu \) being in general unequal, though in some cases two of them may have the same value. For crystalline bodies the value of the \( + \) or \( - \) is nearly always small and constant, the magnetic susceptibility therefore independent of the orientation of the body and proportional to the force. Hence, whatever the position of the body, if the field be resolved into three components parallel to the principal axes of the crystal, the actual magnetization will be the resultant of the three magnetizations along the axes. The body (or each element of it) will tend to set itself with its axis of greatest susceptibility parallel to the lines of force, while, if the field is not uniform, each volume-element will also tend to move towards places of greater or smaller force (according as the substance is paramagnetic or diamagnetic), the tendency being a maximum when the axis of greatest susceptibility is parallel to the field, and a minimum when it is perpendicular to it. The phenomena may therefore be exceedingly complicated.\(^6\)

**3. Magnetic Measurements**

**Magnetic Moment.**—The moment of a magnet may be determined in many ways,\(^7\) the most accurate being that of C. F. Gauss, in which the value of the moment of the magnetometer \( M \) is found by suspending the magnet horizontally, and causing it to vibrate in small arcs. If \( A \) is the moment of inertia of the magnet, and \( t \) the time of a complete vibration, \( M = \pi^2 A/t^2 \) (torsion being neglected). The ratio \( M/H \) is then found by one of the magnetometric methods which in their simplest forms are described below. Equation (44) shows that as a first approximation:

\[
M_H = \pi a d^2 r \tan \theta d / d
\]

where \( l \) is half the length of the magnet, which is placed in the "broadside-on" position as regards a small suspended magnetic needle, \( d \) the distance between the centre of the magnet and the needle, and \( \theta \) the angle through which the needle is deflected by the magnet. We get therefore:

\[
M = \frac{M_H}{H} d / d = \pi a d^2 r \tan \theta / d
\]

When a high degree of accuracy is required, the experiments and calculations are less simple, and various corrections are applied. The moment of a magnet may also be deduced from a measurement of the couple exerted on the magnet by a uniform field \( H \). Thus if the magnet is suspended horizontally by a fine wire, which, when the magnetic axis points north and south, is free from torsion, and if \( \theta \) is the angle through which the upper end of the wire must be twisted to make the magnet point east and west, \( H = M / \cos \theta \), or \( M = \pi a d^2 r \tan \theta / \cos \theta \), whence \( C = \cos \theta \), or \( M = \pi a d^2 r \tan \theta / \cos \theta \).

A bilateral suspension is sometimes used instead of a single wire. If \( P \) is the weight of the magnet, \( l \) the length of each of the two threads, \( 2a \) the distance between their upper points of attachment, and \( 2b \) that between the lower points, then, approximately,

\[
M_H = \frac{P a b}{2 \cos \theta} / d
\]

It is often sufficient to find the ratio of the moment of one magnet to that of another. If two magnets having moments \( M_1 \) and \( M_2 \) are arranged at right angles to each other upon a horizontal support which is free to rotate, their resultant \( R \) will set itself in the magnetic meridian. Let \( \theta \) be the angle which the standard magnet \( M_1 \) makes with the meridian, then \( R = \cos \theta \), and \( M_1 = \cos \theta \), whence \( M_1 = \cos \theta \).

A convenient and rapid method of estimating a magnetic moment has been devised by H. Armagnat.\(^8\) The magnet is laid on a table with its north pole pointing northwards, a compass having a very short needle is placed on the line which bisects the axis of the magnet at right angles, and is moved until a neutral point is found where the force due to the earth's field is balanced by that due to the magnet. If \( 2l \) is the distance between the poles \( m \) and \( n \), the distance from either pole to a point \( P \) on the line AB (fig. 5), we have for the resultant force at \( P \):

\[
R = -2m d / d = -2m d / d = -M d / d
\]

When \( P \) is the neutral point, \( H = \) equal and opposite to \( H' \); therefore \( M = H d / d \), or the moment is numerically equal to the cube of the distance from the neutral point to a pole, multiplied by the height of the pole.\(^9\)

Fig. 5.
MAGNETIC MEASUREMENTS

MAGNETISM

horizontal intensity of the earth's force. The distance between the poles may with sufficient accuracy for a rough determination be assumed to be equal to five-sixths of the length of the magnet.

Measurement of Magnetization and Induction.—The magnetic condition assumed by a piece of ferromagnetic metal in different circumstances is determinable by various modes of experiment which may be classed as magnetometric, ballistic, and traction methods. When either the magnetization I or the induction B corresponding to a given magnetizing force H is known, the other may be found by means of the formula \( B = 4\pi I + H \).

Magnetometric Methods.—Intensity of magnetization is most directly measured by observing the action which a magnetized body, generally a long straight rod, exerts upon a small magnetic needle placed near it. The magnetic needle may be cemented horizontally across the back of a little plane or concave mirror, about 1 cm in diameter, which is suspended by a single fibre of unspun silk; this arrangement, when enclosed in a case with a glazed front to protect it from currents of air, constitutes a simple but efficient magnetometer. Deflections of the suspended needle are indicated by the movement of a narrow beam of light which the mirror reflects from a lamp and focuses upon a graduated cardboard scale placed at a distance of a few feet; the angular deflection of the beam of light is, of course, twice that of the needle. The suspended needle is, in the absence of disturbing causes, directed solely by the horizontal component of the earth's field of magnetic force \( H_e \); and therefore sets itself approximately north and south. The magnetized body which is to be tested should be placed in such a position that the force \( H_e \) due to its poles may, at the spot occupied by the suspended needle, act in a direction at right angles to that due to the earth—that is, east and west. The direction of the resultant field of force will then make, with that of \( H_e \), an angle \( \theta \), such that \( H_e/H = \tan \theta \), and the suspended needle will be deflected through the same angle. We have therefore

\[ H = H_e \tan \theta \]

The angle \( \theta \) is indicated by the position of the spot of light upon the scale, and the horizontal intensity of the earth's field \( H_e \) is known; thus we can at once determine the value of \( H_e \), from which the magnetization \( I \) of the body under test may be calculated.

In order to fulfil the requirement that the field which a magnetized rod produces at the magnetometer shall be at right angles to that of the earth, the rod may be conveniently placed in any one of three different positions with regard to the suspended needle.

1. The rod is set in a horizontal position level with the suspended needle, its axis being in a line which is perpendicular to the magnetic meridian, and which passes through the centre of suspension of the needle. This is called the "upright" position, and is indicated in fig. 6. \( M \) is the rod, \( C \) the middle point of its axis; \( N \) is the magnetometer needle; \( AM \) being the undeflected needle \( N \) at right angles. Let \( 2L = l \) be the length of the rod (or more accurately, the distance between its poles), \( v \) its volume, \( m \) and \( -m \) the strength of its poles, and let \( d \) be the distance \( CM \). For most purposes the length of the needle may be assumed to be negligible in comparison with the distance between the needle and the rod. We then have approximately for the field at \( M \) due to the rod

\[ H = \frac{m}{(dL)^2} - \frac{m}{(dL)^2} = \frac{m}{(dL)^2} \times \frac{4dl}{2d} \]

Therefore \( 2mdl = M = \frac{m}{(dL)^2} \times \frac{4dl}{2d} \) \( \tan \theta \).

And

\[ I = \frac{m}{(dL)^2} \times \frac{4dl}{2d} \tan \theta \]

whence we can find the values of \( I \) which correspond to different angles of deflection.

2. The rod may be placed horizontally east and west in such a position that the direction of the undeflected suspended needle bisects it at right angles. This is known as the "broadside-on" position, and is represented in fig. 7. Let the distance of each pole of the rod \( AB \) from the centre of the magnetometer needle \( = d \). Then, since \( H_e \), the force at \( M \) due to \( m \) and \( -m \), is the resultant of \( m \) and \( -m \), we have

\[ \frac{H_e}{m} = \frac{2l}{d} \]

or

\[ H_e = \frac{2ml}{d^2} \]

the direction being parallel to \( AB \).

And

\[ I = \frac{d\theta H_e}{v} = \frac{d\theta m}{2d} \tan \theta \] (46)

(3) In the third position the test rod is placed vertically with one of its poles at the level of the magnetometer needle, and in the line drawn perpendicularly to the undeflected needle from its centre suspended. The arrangement is shown in fig. 8, where \( AB \) is the rod and \( M \) indicates the position of the magnetometer needle, which is supposed to be perpendicular to the plane of the paper. Denoting the distance \( AM \) by \( d_1 \), \( BM \) by \( d_2 \) and \( AB \) by \( h \), we have for the force at \( M \) due to the magnetism of the rod

\[ H_e = \frac{m}{a_2} \tan \theta \]

\[ = \frac{m}{a_2} \left( \frac{d_1}{d_2} \right) \tan \theta \]

Therefore

\[ m = \frac{1}{a_2} \frac{d_2}{d_1} \frac{d_1}{d_2} \frac{\tan \theta}{\tan \theta} \]

and

\[ I = \frac{dH_e}{v} = \frac{dH_e}{v} \left( \frac{d_2}{d_1} \right) \]

This last method of arrangement is called by Ewing the "one-pole" method, because the magnetometer deflection is mainly caused by the upper pole of the rod (Magnetic Induction, p. 40). For experiments with long thin rods or wires it has an advantage over the other arrangements in that the position of the poles need not be known with great accuracy, a small upward or downward displacement having little effect upon the magnetometer deflection. On the other hand, a vertically placed rod is subject to the inconvenient effect of being placed in an earth's magnetic field which is not the case when the rod is horizontal and at right angles to the magnetic meridian. This extraneous influence may, however, be eliminated by surrounding the rod with a coil of wire carrying a current such as will produce in the interior a magnetic field equal and opposite to the vertical component of the earth's field.

If the cardboard scale upon which the beam of light is reflected by the magnetometer mirror is a flat one, the deflections as indicated by the movement of the spot of light are related to the actual deflections of the needle in the ratio of \( \tan 2\theta \) to \( \theta \). Since \( \theta \) is always small, sufficiently accurate results may generally be obtained if we assume that \( \tan 2\theta = 2\tan \theta \). Therefore the distance of the mirror from the scale is equal to \( n \) scale divisions, and if a deflection \( \theta \) of the needle causes the reflected spot of light to move over \( s \) scale divisions, we shall have

\[ 2\tan \theta = \tan 2\theta = \frac{s}{2} \]

\[ \tan \theta = \tan \theta \]

We may therefore generally substitute \( 2\tan \theta \) for \( \tan \theta \) in the various expressions which have been given for \( I \).

Of the three methods which have been described, the first two are generally the most suitable for determining the moment or the magnetization of a permanent magnet, and the last for studying the changes which occur in the magnetization of a long rod or wire when subjected to various external magnetic forces, or, in other words, for determining the relation of \( I \) to \( H \). A plan of the apparatus as arranged by Ewing for the latter purpose is shown diagrammatically in fig. 9. The cardboard scale \( SS \) is placed above a wooden screen, having in it a narrow vertical slit which permits a beam of light from the lamp \( L \) to reach the mirror of the magnetometer \( M \), whence it is reflected upon the scale. \( A \) is the upper end of a glass tube, half a metre or so in length, which is clamped in a vertical position behind the magnetometer. The tube is wound over its whole length with two separate coils of insulated wire, the one being outside the other. The inner coil is supplied, through the intervening apparatus, with current from the battery of secondary cells \( B \); this produces the desired magnetic field inside the tube. The outer coil derives current, through an adjustable resistance \( R \), from a
constant cell $B_2$; its object is to produce inside the tube a magnetic field equal and opposite to that due to the earth's magnetism. C is a "compensating coil" consisting of a few turns of wire through which the magnetizing current passes; it serves to neutralize the effect produced upon the magnetometer by the magnetizing coil, and its distance from the magnetometer is so adjusted that when the circuit is closed, no ferromagnetic body is retained by the magnetizing coil, the magnetometer needle undergoes no deflection. $K$ is a compensating coil when reversing the direction of the magnetizing current, and $G$ a galvanometer for measuring the deflections.

The strength of the magnetizing current is regulated by adjusting the position of the sliding contact $E$ upon the resistance $DF$. The current increases to a maximum as $E$ approaches $F$, and diminishes to a minimum when $E$ is up to $D$; it can be completely interrupted by means of the switch $H$. The specimen upon which an experiment is to be made generally consists of a wire having a "dimensional ratio" of at least 300 or 400; its length should be rather less than that of the magnetizing coil, in order that the field $H_0$ to which it is subjected, may be approximately uniform from end to end. The wire is supported inside the glass tube $A$ with its upper pole at the same height as the magnetometer needle. Various currents are then passed through the magnetizing coil, the galvanometer readings and the simultaneous magnetometer deflections being noted. From the former we deduce $H_0$ and from the latter the corresponding value of $I$, using the formulae $H_0 = 4\pi s/i$ and

$$I = \frac{dH_0}{2\pi r} \times s, \quad (48)$$

where $s$ is the deflection in scale-divisions, $r$ the distance in scale-divisions between the scale and the mirror, and $r$ the radius of the wire.

The curve, fig. 10, shows the result of a typical experiment made upon a piece of iron (D'Arsonval, Phil. Mag., vol. cxxi., P. 59), the reset magnetizing field $H_0$ being first gradually increased and then diminished to zero. When the length of the wire exceeds 400 diameters, or thereabouts, $H_0$ may generally be considered as equivalent to $H_0$ itself.

The actual strength of the field as modified by the magnetization of the wire, but if greater than $H_0$, is equal to $H_0 - 4\pi s/I$, may be found by the help of de Bois's table and subtracted from $H_0$. For a ratio of 400, $N = 0.00028$, and therefore $H = H_0 - 0.00028 I$. This correction may be indicated in the diagram by a straight line drawn from $D$ through the point at which the line of $I = 1000$ intersects that of $H = 0.028$ (Rayleigh, Phil. Mag. xxii. 175), the true value of $H$ for any point on the curve being that measured from the sloping line instead of from the vertical axis. The effect of the ends of the wire is, as Ewing remarks, to show the deflection in the horizontal direction through the angle which the sloping line makes with the vertical. Since the induction $B$ is equal to $H + 4\pi I$, it is easy from the results of experiments such as that just described to deduce the relation between $B$ and $H$; a curve indicating such a relation is called a curve of induction. The general character of curves of magnetization and of induction will be discussed later. A notable feature in both classes of curves is that, owing to hysteresis, the ascending and descending limbs do not coincide, but follow very different courses. If it is desired to annul the hysteretic effects of previous magnetization and restore the metal to its original condition, it may be demagnetized by reversals. This is effected by slowly moving the sliding contact $E$ (fig. 9) from $F$ to $D$, while at the same time the commutator $K$ is rapidly worked, a series of alternating currents of gradually diminishing strength thus caused to pass through the magnetizing coil.

The magnetometric method, except when employed in connection with ellipsoids, for which the demagnetizing factors are accurately known, is generally less satisfactory for the exact determination of induction or magnetization than the ballistic method. But for much important experimental work it is better adapted than any other, and is indeed sometimes the only method possible.1

1 Ballistic Methods.—The so-called "ballistic" method of measuring induction is based upon the fact that a change of the induction through a closed linear conductor sets up in the conductor an electromotive force which is proportional to the rate of change. If the conductor consists of a coil of wire the ends of which are connected with a suitable galvanometer, the integral electromotive force due to a sudden increase or decrease of the induction through the coil displaces in the circuit a quantity of electricity $Q = 69B$ s R, where $Q$ is the increment or decrement of induction per square centimetre, $s$ is the area of the coil, $n$ the number of turns of wire, and $R$ the resistance of the circuit. Under the influence of the transient current, the galvanometer needle undergoes a momentary deflection, or "throw," which is proportional to $Q$, and therefore to $B$, and thus, if we know the deflection produced by the discharge through the galvanometer of a given quantity of electricity, we have the means of determining the value of $B$. The galvanometer which is used for ballistic observations should have a somewhat heavy needle with a period of vibration of not less than five seconds, so that the transient current may have ceased before the swing has well begun; an instrument of the d'Arsonval type is best used, not only because it is usually placed outside of any other magnetic influence, but also because the moving part can be instantly brought to rest by means of a short-circuit key, thus effecting a great saving of time when a series of observations is being made. In practice it is useless to standardize or "callibrate" the galvanometer by causing a known change of induction to take place within a standard coil connected with it, and noting the corresponding deflection on the galvanometer scale. Let $s$ be the area of a single turn of the standard coil, $n$ the number of turns of its wire, $e$ its resistance, $E$ the electromotive force of the induction $B$, and let $s$, $n$ and $R$ be the corresponding constants for a coil which is to be used in an experiment. Then if a known change of induction $\delta B$ inside the standard coil is found to cause a throw of $\delta$ scale divisions, any change of induction $\delta B$ through the experimental coil will be numerically equal to the corresponding throw $D$ multiplied by $sn\delta B/sn\delta R$. For a series of experiments made with the same coil this fraction is constant, and we may write $\delta B = K$. Rowland and others have used an earth coil for calibrating the galvanometer, a known change of induction through the coil being produced by turning it over in the earth's magnetic field, but for several reasons it is preferable to employ an electric current as the source of a known induction. A primary coil of long length, having a large number of turns, is wound of non-conducting and non-magnetic material, and upon the middle of the primary a secondary induction coil is closely fitted. When a current of strength $s$ is suddenly interrupted in the primary, the induction through the secondary coil is equal to $sn\delta R$ units. All the data required for standardizing the galvanometer can in this way be determined with accuracy.

The ballistic method is largely employed for determining the relation of induction to magnetizing force in samples of the iron and steel used in the manufacture of electrical machinery, and especially for the observation of hysteresis effects. The sample may have the form of a closed ring, upon which are wound the induction coil and another coil for taking the magnetizing current; or it may consist of a long straight rod or wire which can be slipped into a magnetizing coil such as is used in magnetometric experiments, the induction coil being wound upon the middle of the wire. With these arrangements there is no demagnetizing force to be considered, for the ring has not any ends to produce one, and the force due to the ends of a rod 400 or 900 diameters in length is quite insensible in the middle portion; if $H_0$ therefore is equal to $H_0$ itself.

E. Grassot has devised a galvanometer, or "flashmeter," which greatly alleviates the tediousness involved in taking ballistic readings.2 The instrument is of the d'Arsonval type; its coil turns in a strong uniform field, and is suspended in such a manner that torsion is practically negligible, the swings of the coil being limited by damping influences, chiefly electromagnetic. The index therefore remains almost stationary at the limit of its deflection, and the deflection is approximately the same whether the change of induction occurs suddenly or gradually.

Induction and Hysteresis Curves.—Some typical induction curves, copied from a paper by Ewing (Proc. Inst. C.E. vol. cxviii.), are given in figs. 11, 12 and 13. Fig. 11 shows the relation of B to H in a specimen which has never before been magnetized. The experiment may be made in two different ways: 

1. The magnetizing current is increased by a series of sudden steps, each of which produces a ballistic throw, the value of B after any one throw being proportional to the sum of that and all the previous throws; 

2. The magnetizing current having been brought to any desired value, is suddenly reversed, and the observed throw taken as measuring twice the actual induction. Fig. 12 shows the nature of the curve taken by the constant current, after having been raised to the value corresponding to the point a, is diminished by steps until it is nothing, and then gradually increased in the reverse direction. The same process is, in every case of hysteresis, strikingly different from its upward course, and when the magnetizing force has been reduced to zero, there is still remaining an induction of 7500 units. If the operation is again reversed, the upward course will be nearly, but not exactly, of the form shown by the line d e a, fig. 13. After a few repetitions of the reversal, the process becomes strictly cyclic, the upward and downward curves always following with precision the paths indicated in the figure. In order to establish the cyclic condition, it is sufficient to apply alternately the greatest positive and negative forces employed in the test (greatest H = about ± 5 C.G.S. units in the case illustrated in the figure), an operation which is performed by simply reversing the direction of the maximum magnetizing current a few times.

The closed curve a c d e a is variously called a hysteresis curve or diagram or loop. The area \( \frac{1}{4} \pi HdB \) enclosed by it represents the work done in carrying a cubic centimetre of the iron through the corresponding magnetic cycle; expressed in ergs this work is

\[ \frac{1}{4} \pi HdB. \]

To quote an example given by J. A. Fleming, it requires about 18 foot-pounds of work to make a complete magnetic cycle in a cubic foot of wrought iron, strongly magnetized first one way, and then the other, the work so expended taking the form of heat and light.

Fig. 14 shows diagrammatically a convenient arrangement described by Ewing (see Proc. Inst. C.E. vol. cxviii., and Phil. Trans. 1893 A, p. 957) for carrying out ballistic tests by which either the simple B-H curve (fig. 11) or the hysteresis curve (figs. 12 and 13) can be determined. The sample under test is prepared in the form of a ring A, upon which are wound the induction and the magnetizing coils; the latter should be wound evenly over the whole ring, though for the sake of clearness only part of the winding is indicated in the diagram. The magnetizing current, which is derived from the large battery B, is regulated by the adjustable resistance R and measured by the galvanometer G. The current passes through the rocking key K, which, when thrown over to the right, places a in contact with d and f; when thrown over to the left, places e in contact with e and f. When the switch S is closed, K acts simply as a commutator or current-reverser, but if K is thrown over from right to left while S is opened, not only is the current reversed, but its strength is at the same time diminished by the interposition of the adjustable resistance R. The induction coil wound upon the ring is connected to the ballistic galvanometer G in series with a large permanent resistance R. In the same circuit is also included the induction coil E, which, when used for standardizing the galvanometer, this secondary coil is represented in the diagram by three turns of wire wound over a much longer primary coil. The short-circuit key F is kept closed except when an observation is about to be made; its object is to arrest the swing of the d'Arsonval galvanometer G. By means of the three-way switch C the battery current may be sent either into the primary of E, for the purpose of calibrating the galvanometer, or into the magnetizing coil of the ring under test. When it is desired to obtain a simple curve of induction, such as that in fig. 11, S is permanently closed, and corresponding values of H and B are determined by one of the two methods already described, the strength of the battery-current being varied by means of the adjustable resistance R. When a hysteresis curve is desired, the key K is first adjusted by means of R such as will fit it to produce the greatest + and − values of the hysteresis force which it is intended to apply in the course of the cycle; then it is reversed several times, and when the range of the galvanometer throws has become constant, half of an excursion indicates the induction corresponding to the extreme value of H, and gives the point a in the curve fig. 12. The reversing key K having been taken to the left side, the short-circuit key S is suddenly opened; this inserts the resistance R, which has been suitably adjusted beforehand, and thus reduces the current and therefore the magnetizing force to a known value. The galvanometer then records the results from the change of current measures the amount by which the induction is reduced, and thus a second point on the curve is determined. In a similar manner, by giving different values to the resistance R, any desired number of points between a and c in the curve can be determined. To continue the process, the key K is turned over to the right-hand side, and then, while S is open, is turned back, thereby not only reversing the direction of the current, but diminishing its strength by an amount depending upon the previous adjustment of R. In this way points can be found lying anywhere between c and d of fig. 12, and the determination of the downward limb of the curve is therefore completed. As the return curve, shown in fig. 13, is merely an inverted copy of the other, no separate determination of it is necessary.

In fig. 15 (J. A. Fleming, Magnets and Electric Currents, p. 193) are shown three very different types of hysteresis curves, characteristic of the special qualities of the metals from which they were respectively obtained. The distinguishing feature of the first is the steepness of its outlines; this indicates that the induction increases rapidly in relation to the magnetic force, and hence the metal is well suited for the construction of dynamos. The second has a very small area, showing that the work done in reversing the magnetization is small; the metal is therefore adapted for use in alternating current transformers. On the other hand, the form of the third curve, with its large intercepts on the axes of H and B, denotes that the specimen to which it relates possesses both retentiveness and coercive force in a high degree; such a metal would be chosen for making good permanent magnets.

Several arrangements have been devised for determining hysteresis more easily and expeditiously than is possible by the ballistic method. The best known is J. A. Ewing's hysteresis-tester, which is specially intended for testing the sheet iron used in transformers. The sample, arranged as a bundle of rectangular strips, is caused to rotate about a central horizontal axis between the poles of an upright C-shaped magnet, which is supported near its middle upon knife edges in such a manner that it can oscillate about an axis in line with that about which the specimen rotates; the lower side of the magnet is weighted, to give it some stability. When the specimen rotates, the magnet is deflected from its upright position by a small angle which the work done in a single complete rotation, and therefore upon the hysteresis. The deflection is indicated by a pointer upon a graduated scale, the readings being interpreted by comparison with two standard specimens supplied with the instrument. G. F. Searle and T. G. Bedford have

---

1 Magnetic Induction, 1900, 378.
2 Phil. Trans., 1902, 198, 33.
introduced the method of measuring hysteresis by means of an electro-dynamometer used ballistically. The fixed and suspended coils of the dynamometer are respectively connected in series with the magnetizing solenoid and with a secondary wound upon the specimen. When the magnetizing current is twice reversed, so as to complete a cycle, the sum of the two deflections, multiplied by a factor depending upon the sectional area of the specimen and upon the constants of the apparatus, gives the hysteresis for a complete cycle in ergs per cubic centimetre. For specimens of large sectional area it is necessary to apply corrections in respect of the energy dissipated by eddy currents and in heating the secondary circuit. The method has been employed by the authors themselves in studying the effects of tension, torsion and circular magnetization, while R. L. Wills\(^1\) has made successful use of it in his research on the effects of temperature, a matter of great industrial importance.

C. P. Steinmetz (Electrician, 1891, 26, p. 261; 1892, 28, pp. 384, 408, 425) has called attention to a simple relation which appears to exist between the amount of energy dissipated in carrying a piece of iron or steel through a magnetic cycle and the limiting value of the induction reached in the cycle. Denoting by \(W\) the work in ergs done upon a cubic centimetre of the metal

\[
\left( = \frac{1}{4} \int H dB \text{ or } \int H dI \right),
\]

he finds \(W = \eta B^4\) approximately, where \(\eta\) is a number, called the \textit{hysteric constant}, depending upon the metal, and \(B\) is the maximum induction. The value of the constant \(\eta\) ranges in different metals from about 0.001 to 0.04; in soft iron and steel it is said to be generally not far from 0.002. Steinmetz’s former expression was tested by taking a series of hysteresis curves between different limits of \(B\), measuring their areas by a planimeter, and plotting the logarithms of these divided by \(4\pi\) as ordinates against logarithms of the corresponding maximum values of \(B\) as abscissae. The curve thus constructed should be a straight line inclined to the horizontal axis at an angle \(\theta\), the tangent of which is \(1/\eta\). Ewing and H. G. Klaassen (Phil. Trans., 1893, 184, 1017) have in this manner examined how nearly and within what range a formula of the type \(W = \eta B^4\) may be taken to represent the facts. The results of an example which they quote in detail may be briefly summarized as follows:

It is remarked by the experimenters that the value of the index \(\epsilon\) is by no means constant, but changes in correspondence with the successive well-marked stages in the process of magnetization. But though a formula of this type has no physical significance, and cannot be accepted as an equation to the actual curve of \(W\) and \(B\), it is, nevertheless, the case that by making the index \(\epsilon = 1.6\), and assigning a suitable value to \(\eta\), a formula may be obtained which is sufficiently close for the ordinary purposes of electrical engineers, especially when the limiting value of \(B\) is neither very great nor very small. Alexander Siemens (Journ. Inst. Eng., 1894, 23, 229) states that in the hundreds of comparisons of test pieces which have been made at the works of his firm, Steinmetz’s law has been found to be practically correct.\(^2\) An interesting collection of \(W-B\) curves embodying the results of actual experiments by Ewing and Klaassen on different specimens of metal is given in fig. 16. It has been shown by Kennelly (Electrician, 1892, 28, 666) that Steinmetz’s formula gives approximately correct results in the case of nickel. Working with two different specimens, he found that the hysteresis loss in ergs per cubic centimetre \((W)\) was fairly represented by \(W = 0.001 B^4\) and \(0.00001 B^4\) respectively, the maximum induction ranging from about 300 to 3000. The applicability of the law to cobalt has been investigated by Fleming (Phil. Mag., 1899, 48, 271), who used a ring of cast cobalt containing about 96% of the pure metal. The logarithmic curves which accompany his paper demonstrate that within wide ranges of maximum induction \(W = 0.010 B^4 = 0.5271\) are very nearly, Fleming rightly regards it as not a little curious that for materials differing so much as this cast cobalt and soft iron the hysteresis curve in both cases is so nearly \(1.6\). After pointing out that, since the magnetization of the metal is the quantity really concerned, \(W\) is more appropriately expressed in terms of \(I\), the magnetic moment per unit of volume, that is to say, a somewhat stronger attempt to determine whether the mechanical work required to effect the complete magnetic reversal of a crowd of small compass needles (representative of magnetic molecules) is proportional to the 1.6th power of the aggregate maximum magnetic moment before or after completion of the cycle.

\(^1\) Phil. Mag., 1903, 5, 117.
\(^2\) Some experiments by F. G. Baily showed that hysteresis ceased to increase when \(B\) was carried beyond 23,000. This value of \(B\) corresponds to \(I = 1640\), the saturation point for soft iron.—Brit. Assoc. Rep., 1895, p. 636.

The experiments of K. Honda and S. Shimizu\(^3\) indicate that Steinmetz’s formula holds for nickel and annealed cobalt up to \(B = 3000\), for cast cobalt and tungsten steel up to \(B = 8000\), and for Swedish iron up to \(B = 18000\), the range being in all cases extended at the temperature of liquid air.

The diagram, fig. 17, contains examples of ascending induction curves characteristic of wrought iron, cast iron, cobalt and nickel.

MAGNETISM

Low hysteresis is the chief requisite for iron which is to be used for transformer cores, and it does not necessarily accompany high permeability. In response to the demand, manufacturers have succeeded in producing transformer plate in which the loss of energy due to hysteresis is exceedingly small. Tests of a sample supplied by Messrs. Sankey were found by Ewing to give the following results, which, however, are regarded as being unusually favourable. In a valuable collection of magnetic data (Proc. Inst. C.E., xxvii.) H. F. Parshall quotes tests of six samples of iron, described as of good quality, which showed an average hysteresis loss of 3070 ergs per c.cm. per cycle at an induction of 8000, being on 6 times the loss shown by Ewing's specimen at the same induction.

The standard induction in reference to determinations of hysteresis is generally taken as 2500, while the loss is expressed in watts per lb at a frequency of 100 double reversals, or cycles, per second. In many experiments, however, different inductions and frequencies are employed, and the hysteresis-loss is often expressed as ergs per cubic centimetre per cycle and sometimes as horse-power per ton. In order to save arithmetical labour it is convenient to be provided with conversion factors for reducing variously expressed results to the standard form. The rate at which energy is lost being proportional to the frequency, it is obvious that the loss at frequency 100 may be deduced from that at any other frequency by simply multiplying by 100. Taking the density of iron to be 27, the factor for reducing the loss in ergs per c.cm. to watts per lb with a frequency of 100 is 0.000589 (Ewing). Since 1 horse-power = 746 watts, and 1 ton = 2240 lb, the factor for reducing horse-power per ton to watts per lb is 746/2240, or just 1/3. The loss for any induction B within the range for which Steinmetz's law holds may be converted into that for the standard induction 2500 by dividing it by $B^2/2500^2$. The values of this ratio for different values of B, as given by Fleming (Phil. Mag., 1897), are contained in the second column of the annexed table. The third column shows the relative amount of hysteresis deduced by Ewing as a general mean from actual tests of many samples (Journ. Inst. Elect. Eng., 1895). Incidentally, these two columns furnish an undesignated test of the accuracy of Steinmetz's law: the greatest difference is little more than 1%.

Curves of Permeability and Susceptibility.—The relations of $\mu (= B/H)$ to $B$, and of $\kappa = (1/H)$ to $I$ may be instructively exhibited by means of curves, a method first employed by H. A. Rowland. The dotted curve for $\mu$ and $B$ in fig. 18 is copied from Rowland's paper. The actual experiment to which it relates was carried out only as the point marked X, corresponding to a magnetizing force of 65, and an induction of nearly 17,000. It was decided that the curve would continue to fall in a straight line meeting the horizontal axis, inferred that the induction corresponding to the point B about 17,500 was the highest

To secure the highest possible permeability it is essential that the iron should be softened by careful annealing. When it is mechanically hardened by hammering, rolling or wire-drawing its permeability may be greatly diminished, especially under a moderate magnetizing force. An experiment by Ewing showed that by the operation of stretching an annealed iron wire beyond the limits of elasticity the permeability under a magnetizing force of about 3 units was reduced by as much as 75%. Ewing has also studied the effect of vibration in conferring upon iron an apparent or spurious permeability of high value; this effect also is most conspicuous when the magnetizing force is weak. The permeability of a soft iron wire, which was tapped while subjected to a very small magnetizing force, rose to the enormous value of about 80,000 (Magnetic Induction, § 8). It follows that in testing iron for magnetic quality the greatest care must be exercised to guard the specimen against any accidental vibration.

at the right-hand side of the diagram, the greatest error introduced by neglecting $H/\pi$ not exceeding $0.6\%$. A study of such curves as these reveals the fact that there are three distinct stages in the process of magnetization. During the first stage, when the magnetizing force is small, the magnetization (or the induction) increases rather slowly with increasing force; this is well shown by the nickel curve in the diagram, but the effect would be no less conspicuous in the iron curve if the abscissae were plotted to a larger scale. During the second stage small increments of magnetizing force are attended by relatively large increments of magnetization, as is indicated by the steep ascent of the curve. Then the curve bends over, forming what is often called a "knee," and a third stage is entered upon, during which a considerable increase of magnetizing force has little further effect upon the magnetization. When in this condition the metal is popularly said to be "saturated." Under increasing magnetizing forces, greatly exceeding those comprised within the limits of the diagram, the magnetization does practically reach a limit, the maximum value being attained with a magnetizing force of less than 2000 for wrought iron and nickel, and less than 4000 for cast iron and cobalt. The induction, however, continues to increase indefinitely, though very slowly. These observations have an important bearing upon the molecular theory of magnetism, which will be referred to later.

The magnetic quality of a sample of iron depends very largely upon the purity and physical condition of the metal. The presence of ordinary impurities usually tends to diminish the permeability, though, as will appear later, the addition of small quantities of certain other substances is sometimes advantageous. A very pure form of iron, which from the method of its manufacture is called "steel," is now extensively used for the construction of dynamo magnets; this metal sometimes contains not more than $0.3\%$ of foreign substances, including carbon, and is magnetically superior to the best commercial wrought iron. The results of some comparative tests published by Ewing (Proc. Inst. C.E., 1860) are given in the accompanying table. Those in the second column are quoted from a paper by J. Lydall and A. W. Pocklington (Proc. Roy. Soc., 1893, 52, 228) and relate to an exceptional specimen containing nearly $99.9\%$ of the pure metal.

To secure the highest possible permeability it is essential that the iron should be softened by careful annealing. When it is mechanically hardened by hammering, rolling or wire-drawing its permeability may be greatly diminished, especially under a moderate magnetizing force. An experiment by Ewing showed that by the operation of stretching an annealed iron wire beyond the limits of elasticity the permeability under a magnetizing force of about 3 units was reduced by as much as 75%. Ewing has also studied the effect of vibration in conferring upon iron an apparent or spurious permeability of high value; this effect also is most conspicuous when the magnetizing force is weak. The permeability of a soft iron wire, which was tapped while subjected to a very small magnetizing force, rose to the enormous value of about 80,000 (Magnetic Induction, § 8). It follows that in testing iron for magnetic quality the greatest care must be exercised to guard the specimen against any accidental vibration.
that could be produced by any magnetizing force, however great. It has, however, been shown that, if the magnetizing force is carried far enough, the curve always becomes convex to the axis instead of meeting it. The full line shows the result of an experiment in which the magnetizing force was carried up to 585,\footnote[1]{S. Bidwell, Proc. Roy. Soc., 1886, 40, 495.} but though the force was thus increased ninefold, the induction only reached 10,800, and the ultimate value of the permeability was still as much as 33.9.

**Ballistic Method with Yoke.**—J. Hopkinson (Phil. Trans., 1885, 176, 455) introduced a modification of the usual ballistic arrangement which presents the following advantages: (1) very considerable magnetizing forces can be applied with ordinary means; (2) the samples to be tested, having the form of cylindrical bars, are more easily prepared than rings or wires; (3) the actual induction at any time can be measured, and not only changes of induction. On the other hand, a very high degree of accuracy is not claimed for the results. Fig. 19 shows the apparatus by which the ends of the bar are prevented from exerting any material demagnetizing force, while the permeance of the magnetic circuit is at the same time increased. A, called the “yoke,” is a block of annealed wrought iron about 18 in. long, 63 in. wide and 2 in. thick, through which is cut a rectangular opening to receive the two magnetizing coils B B. The test bar C C, which slides through holes bored in the yoke, is divided near the middle into two parts, the ends which come into contact being faced true and square. Between the magnetizing coils is a small induction coil D, which is connected with a ballistic galvanometer. The induction coil is carried upon the end of one portion of the test bar, and when this portion is suddenly drawn back the coil slips off and is pulled out of the field by an india-rubber spring. This causes a ballistic throw proportional to the induction through the bar at the moment when the two portions were separated. With such an arrangement it is possible to submit the sample to any series of magnetic forces, and to measure its magnetic state at the end. The uncertainty with which the results are affected depends chiefly upon the imperfect contact between the bar and the yoke and also between the ends of the divided bar. It is probable that Hopkinson did not attach sufficient importance to the demagnetizing action of the cut (cf. Ewing, Phil. Mag., Sept. 1888, p. 274), and that the values which he assigned to H are consequently somewhat too high. He applied his method with good effect, however, in testing a large number of commercial specimens of iron and steel, the magnetic constants of which are given in a table accompanying his paper. When it is not required to determine the residual magnetization there is no necessity to divide the sample bar, and ballistic tests may be made in the ordinary way—by steps or by reversals—the source of error due to the transverse cut thus being avoided. Ewing (Magnetic Induction, § 174) has devised an arrangement in which two similar test bars are placed side by side; each bar is surrounded by a magnetizing coil, the two coils being connected to give opposite directions of magnetization, and each pair of ends is connected by a short massive block of soft iron having holes bored through it to fit the bars, which are clamped in position by set-screws. Induction coils are wound on the middle parts of both bars, and are connected in series. With this arrangement it is possible to find the actual value of the magnetizing force, corrected for the effects of joints and other sources of error. Two sets of observations are taken, one when the blocks are fixed at the ends of the bars, and another when they are nearer together, the clear length of the bars between them and of the magnetizing coils being reduced to one-half. If \( H_1 \) and \( H_2 \) be the values of \( 4\pi h/l \) and \( 4\pi\beta^2 /2 \) for the same induction B, it can be shown that the true magnetizing force is \( H = H_1 - (H_2 - H_1) \). The method, though tedious in operation, is very accurate, and is largely employed for determining the magnetic quality of bars intended to serve as standards.

**Traction Methods.**—The induction of the magnetization may be measured by observing the force required to draw apart the two portions of a divided rod or ring when held together by their mutual attraction. If a transverse cut is made through a bar whose magnetization is 1 and the two ends are placed in contact, it can be shown that this force is \( 2\pi R \) dynes per unit of area (Mascart and Joubert, Electricity and Magnetism, § 322; and if the magnetization of the bar is due to an external field \( H \) produced by a magnetizing coil or otherwise, there is an additional force equal to \( H \). Thus the whole force, when the two portions of the bar are surrounded by a loosely-fitting magnetizing coil, is

\[
F = 2\pi R + H
\]

expressed as dynes per square centimetre. If each portion of the bar has an independent magnetizing coil wound tightly upon it, we have further to take into account the force due to the mutual action of the two magnetizing coils, which assists the forces already considered. This is equal to \( H^2 \pi /8 \) per unit of sectional area. In the case supposed therefore the total force per square centimetre is

\[
F = 2\pi R + H + \frac{H^2}{8\pi} - \frac{(4\pi R + H)^2}{8\pi} = \frac{B^2}{8\pi}
\]

The equation \( F = B^2/8\pi \) is often said to express "Maxwell's law of magnetic traction" (Maxwell, Electricity and Magnetism, §§ 642–646). It is, of course, true for permanent magnets, where \( H = \sigma \), since then \( F = 2\pi R \); but if the magnetization is due to electric currents, the formula is only applicable in the special case when the mutual action of the two magnets upon one another is supplemented by the electromagnetic attraction between separate magnetizing coils rigidly attached to them.\footnote[2]{Since in most practicable experiments \( H \) is negligible in comparison with \( B \); the force may be taken as \( B^2/8\pi \) without sensible error.}

The traction method was first employed by S. Bidwell (Proc. Roy. Soc., 1886, 498, 1860), who in 1886 published an account of some experiments in which the relation of magnetization to magnetic field was deduced from observations of the force in grammes weight which just sufficed to tear asunder the two halves of a divided ring electro-magnet when known currents were passing through the coils. He made use of the expression

\[
F = W = 2\pi R + H_1
\]

where \( W \) is the weight in grammes per square centimetre of sectional area, and \( g \) is the intensity of gravity which was taken as 981. The term for the attraction between the coils was omitted as negligibly small (see Phil. Mag., 1890, 29, 446). The values assigned to \( H \) were calculated from \( H = 2\pi R/H \), and ranged from 3.9 to 58, but inasmuch as no account was taken of any
demagnetizing action which might be due to the two transverse cuts, it is probable that they are somewhat too high. The results, nevertheless, agree very well with those for annealed wrought iron obtained by other methods. Below is a given selection from Bidwell’s tables, showing corresponding values of magnetizing force, weight supported, magnetization, induction, susceptibility and permeability:

A few months later R. H. M. Bosanquet (Phil. Mag., 1886, 22, 553) experimented on the relation of the lines of magnetic induction. Instead of a divided ring he employed a divided straight bar, each half of which was provided with a magnetizing coil. The joint was surrounded by an induction coil connected with a ballistic galvanometer, an arrangement which enabled him to make an independent measurement of the induction at the moment when the two portions of the bar were separated.

He showed that there was, on the whole, a fair agreement between the values determined ballistically and those given by the formula \( B = \sqrt{8F} \).

The greatest weight supported in the experiments was 14,000 grammes per square cm., and the corresponding induction 18,900 units. Taylor Jones subsequently found a good agreement between the theoretical and the observed values of the magnetic force in fields ranging up to very high intensities (Phil. Mag., 1895, 30, 234, and 1896, 41, 153).

Permeameters.—Several instruments in which the traction method is applied have been devised for the rapid measurement of induction or of magnetization in commercial samples of iron and steel. The earliest of these is S. P. Thompson’s permeameter (Journ. Sci. Arts, 1888, 382, 266) which consists of a rectangular block of iron, like Hopkinson’s yoke, and slotted out in the same way to receive a magnetizing coil (fig. 20); the block is bored through at the upper end only, and its inner face opposite the hole is made quite flat and smooth. The gap of the other side of the rod is the line of demagnetizing force which is faced true: it is slipped into the magnetizing coil from above, and when the current is turned on its smooth end adheres tightly to the surface of the yoke. The force required to detach it is measured by a règlering spring balance, which is clamped to the upper end of the rod, and thence the induction or the magnetization is deduced by applying the formula

\[
(B-H)/8F = 2\pi P_g = \text{P}g/8,
\]

where \( P \) is the pull in grammes weight, \( S \) the sectional area of the rod in square inches, \( H \) is the average of the pull in pounds at the area in square inches, the formula may be written \( B = 1.17\times\sqrt{F/S} - H \).

The instrument exhibited by Thompson would, without undue heating, take a current of 30 amperes, which was sufficient to produce a magnetizing force of 1000 units. A test piece of the same parameter made by the use of two yokes and a single coil, and each pair of ends is joined by a short rectangular block or “yoke” of soft iron. An iron bar shaped like an inverted \( L \) projects upwards from each of the yokes, the horizontal portions of the bars being parallel and placed nearly in line at a height of about 8 in. above them (thus \( \tau \)). A compass needle placed in the gap serves to detect any flow of induction that may exist between the bars. For simplicity of calculation, the clear length of the magnetizing force, which produce the same induction \( H \), while the coil surrounding the standard bar contains 100 turns; hence the magnetizing force due to a current of \( n \) amperes will be \( 100n \) C.G.S. units. The effective number of turns in the coil surrounding the test rod can be varied by means of three dial switches (for hundreds, tens and units), which also introduce compensating resistances as the number of effective turns in the coil is reduced, thus keeping the total resistance of the circuit constant. The two coils are connected in series and the current passing through both supports the switches to be adjusted so that the effective number of turns in the variable coil is 100; the magnetizing forces in two coils will then be equal, and if the test rod is of the same quality as the standard, the flow of induction will be confined entirely to the primary, the two yokes will be at the same magnetic potential, and the compass needle will not be affected. If, however, the permeability of the test rod differs from that of the standard, the number of lines of induction flowing in opposite directions through the two rods will be different, and the magnetic field will be partly through the air, and partly along the path provided by the bent bars, deflecting the compass needle. But a balance may still be obtained by altering the effective number of turns in the test coil, tilting the induction on the test rod, till the induction in the two rods is the same, a condition which is fulfilled when reversal of the current has no effect on the compass needle. Let \( m \) be the number of turns in use, and \( H_1 \) and \( H_2 \), the magnetizing forces in the test rod, the test and the standard rods respectively; then \( H_1 = H_2 \times m/100 \).

The value of \( B \) which corresponds to \( H/100 \) can be found from the
MAGNETISM

(B, H) curve for the standard, which is assumed to have been determined; and this same value corresponds to the force H in the case of the test bar. Thus any desired number of corresponding values of H and B can be easily and quickly found.

Measurement of Field Strength. Exploring Coil.—Since in air B = H, the ballistic method of measuring induction described above is also available for determining the strength of a magnetic field, and is more often employed than any other. A small coil of fine wire, connected in series with a ballistic galvanometer, is placed in the field, with its windings perpendicular to the lines of force, and then suddenly reversed or withdrawn from the field, the returning electromotive force being twice as great in the first case as in the second. The strength of the field is proportional to the swing of the galvanometer-needle, and, when the galvanometer is calibrated, can be expressed in C.G.S. units. Convenient arrangements have been introduced whereby the coil is reversed or withdrawn from the field by the action of a spring.

Bismuth Resistance.—The fact, which will be referred to later, that the electrical resistance of bismuth is very greatly affected by a magnetic field has been applied in the construction of apparatus for measuring field intensity. A little instrument, supplied by Hartmann and Braun, contains a short length of fine bismuth wire wound into a flat double spiral, half an inch or thereabouts in diameter, and attached to a long ebonite handle. Unfortunately the effects of magnetization upon the specific resistance of bismuth vary enormously with changes of temperature; it is therefore necessary to take two readings of the resistance, one when the spiral is in the magnetic field, the other when it is outside.

Electric Circuit.—If a coil of insulated wire is suspended so that it is in stable equilibrium when its plane is parallel to the direction of a magnetic field, the transmission of a known electric current through the coil will cause it to be deflected through an angle which is a function of the field intensity.

One of the most appeciable applications of this principle is that described by Eder and Stansfield (Phil. Mag., 1893, 34, 1879), and used by them to test the stray fields of dynamos. An oblong coil about an inch in length is suspended from each end by thin strips of rolled German silver wire, one of which is connected with a spiral spring for regulating the tension, the other being attached to a torsion-head. Inside the torsion-head is a commutator for automatically reversing the current, so that readings may be taken on each side of zero, and the arrangement is such that when the torsion-head is exactly at zero the current is interrupted. To take a reading the torsion-head is turned until an aluminium pointer attached to the coil is brought to the zero position on a small scale; the strength of the field is then proportional to the angular torsion. The small current required is supplied from a single dry cell. The advantages of portability, very considerable range (from $H = 1$ upwards), and fair accuracy are claimed for the instrument.

Polarized Light.—The intensity of a field may be measured by the rotation of the plane of polarization of light passing in the direction of the magnetic force through a transparent substance. If the field is uniform, $H = \theta / \omega d$, where $\theta$ is the rotation, $d$ the thickness of the substance arranged as a plate at right angles to the direction of the field, and $\omega$ Verdet's constant for the substance.

For the practical measurement of field intensity du Bois has used plates of clear birefringent Jena flint glass. These are preferably made slightly wedge-shaped to avoid the inconvenience resulting from multiple internal reflections, and they must necessarily be rather thin, so that double refractions due to internal strain may not exert a disturbing influence. Since Verdet's constant is somewhat uncertain for different batches of glass of the same quality, each plate should be standardized in a field of known intensity. As the source of monochromatic light a bright sodium burner is used, and the rotation, which is exactly proportional to $H$, is measured by an accurate optical device. The thickness of the plate is varied to be adapted for measuring fields of the order of 1000 units. A part of one surface of the plate may be silvered, so that the polarized ray, after having once traversed the glass, is reflected back again; the rotation is thus doubled, and moreover, the arrangement is, for certain experiments, more convenient than the other.

4. MAGNETIZATION IN STRONG FIELDS

Fields due to Coils.—The most generally convenient arrangement for producing such magnetic fields as are required for experimental purposes is undoubtedly a coil of wire through which an electric current can be caused to flow. The field due to a coil can be made as nearly uniform as we please throughout a considerable space; its intensity, when the constants of the coil are known, can be calculated with ease and certainty, and may be varied at will through wide ranges, while the apparatus required is of the simplest character and can be readily constructed to suit special purposes. But when exceptionally strong fields are desired, the use of a coil is limited by the heating effect of the magnetizing current, the quantity of heat generated per unit of time in a coil of given dimensions increasing as the area of the magnetic field produced in its interior.

In experiments on magnetic strains carried out by H. Nagaoka and K. Honda (Phil. Mag., 1909, 49, 329) the intensity of the highest field reached in the interior of a coil was 2200 units; this is probably the strongest field produced by a coil which has hitherto been employed in experimental work. In 1893 some experiments in which a coil was used were made by du Bois (Phil. Mag., 1890, 9, 353, 354) on the magnetization of iron, nickel, and cobalt under forces ranging from about 100 to 1250 units. Since the demagnetizing factor was 0.075, the strongest field due to the coil was about 1540; but though arrangements were provided for cooling the apparatus by means of ice, great difficulty was experienced owing to heating. Du Bois's results, which, as given in his papers, show the relation of $H$ to the magnetic moment per unit of mass, have been reduced by Ewing to the usual form, and are indicated in fig. 22, the earlier portions of the curves being sketched in from other data.

Fields due to Electromagnets.—The problem of determining the magnetization of iron and other metals in the strong fields formed between the poles of an electromagnet was first attacked by J. A. Ewing and W. Low. An account of their preliminary experiments by which they call the isthmus method was published in 1887 (Proc. Roy. Soc. 42, 200), and in the following year they described a more complete and perfect series (Phil. Trans., 1889, 150, 221).

The sample to be inserted between the magnet poles was prepared in the form of a bobbin resembling an ordinary cotton reel, with a short angle of $39^\circ$ 44' in the latter case the magnetic force in the air just outside is sensibly equal to that within the neck. A pair of cones having a semi-vertical angle of $45^\circ$ were considered to combine high concentrative power with a sufficient approximation to uniformity of field. In most of the experiments the measurements were made by suddenly withdrawing the bobbin from its place...
between the pole pieces. Two groups of observations were recorded, one giving the induction in the inner coil and the other that in the outer coil. The value of the residual induction which persisted when the bobbin was drawn out was added to that of the induction measured, and thus the total induction in the iron was determined. The highest induction reached in these experiments was 45,350 units, more than twice the value of any previously recorded. The corresponding intensity of the outside field was 24,500, but, owing to the wide angle of the cones used (about 22 60' 90), this was probably greater than the value of the magnetic force within the metal. The following table shows some results of other experiments in which H was believed to have sensibly the same value inside as outside the metal. Values of I are derived from (B-H)/4π and of μ from B/H.

These results are of extreme interest, for they show that under sufficiently strong magnetizing forces the intensity of magnetization I reaches a maximum value, as required by W. E. Weber's theory of molecular magnetism. There appears to be no definite limit to the value to which the induction B may be raised, but the magnetization I attains a true saturation value under magnetizing forces which are in most cases comparatively moderate. Thus the magnetization which the sample of Swedish iron received in a field of 1490 was not increased (beyond the limits of experimental error) when the intensity of the field was multiplied more than thirteen-fold, though the induction was nearly doubled. When the saturation value of I has been reached, the relation of magnetic induction to magnetic force may be expressed by

\[ B = H + \text{constant}. \]

The annexed table gives the saturation values of I for the particular metals examined by Ewing and Low:

It is shown in the paper that the greatest possible force which the isthmal method can apply at a point in the axis of the bobbin is

\[ F = 11-137 I \log_2 b/a, \]

I being the saturation value of the magnet poles, a the radius of the neck on which the cones converge, and b the radius of the bases of the cones.

Some experiments made by H. du Bois (Phil. Mag., 1890, 29, 293) with an electromagnet specially designed for the production of strong fields, confirm Ewing's results for iron, nickel and cobalt. The method employed did not admit of the production of such high magnetizing forces, but was of special interest in that both B and I were measured optically—B by means of the rotation of a polarized ray inside a glass plate, as before described, and I by the rotation of a polarized ray reflected from the polished surface of the magnetized metal (see "Kerr's constant," Magneto-Optics). H = B - σI was calculated from corresponding values of I and B. Taylor Jones (Phil. Mag., 1896, 57, 258, and Phil. Mag., 1896, 41, 153), working with du Bois's electromagnet and using a modification of the isthmal method, succeeded in pushing the induction B up to 74,200 with H = 51,600, the corresponding value of I being 1798, and of μ only 1-44. The diameter of the isthmus was 0-241 mm., and the electromagnet was excited by a current of 40 amperes.

**Tractive Force of a Magnet.**—Closest connected with the results just discussed is the question what is the greatest tractive force that can be exerted by a magnet. In the year 1852 J. P. Joule (Phil. Mag., 1852, 3, 32) expressed the opinion that no "force of current could give an attraction equal to 200 lb per sq. in.," or 14,000 grms. per square centimetre, and a similar view prevailed among high authorities more than twenty years later. For the greatest possible "lifting power" of permanent magnets this estimate is probably not very far from the truth, but it is now clearly understood that the force which can be exerted by an electromagnet, or by a pair of electromagnets with opposite poles in contact, is only limited by the greatest value to which it is practically possible to raise the magnetizing force H. This is at once evident when the tractive force due to magnetization is expressed as \(2π^2H+HI\). For fields of moderate intensity the first term of the expression is the more important, but when the value of H exceeds 12,000 or thereabouts, the second preponderates, and with the highest values that have been actually obtained, H is several times greater than \(2πH\) if H could be increased without limit, so also could the tractive force. The following table shows the greatest "lifting powers" experimentally reached at the dates mentioned:

5. Magnetization in Very Weak Fields

Some interesting observations have been made of the effects produced by very small magnetic forces. It was first pointed out by C. Baur (Phil. Mag., 1880, 11, 399) that in weak fields the relation of the magnetization I to the magnetizing force H is approximately expressed by an equation of the form

\[ I = a_1H + a_2H^2, \]

whence it appears that within the limits of Baur's experiments the magnetization curve is a parabola, and the susceptibility curve an inclined straight line, \(k\) being therefore a known function of H. If these equations could be assumed to hold when H is indefinitely small, it would follow that \(k\) has a finite initial value, from which there would be no appreciable deviation in fields so weak that \(BH\) was negligibly small in comparison with \(a\). Such an assumption could not, however, without dangerous extrapolation, be founded upon the results of Baur's experiments, which did not go far enough to justify it. In some experiments carried out in 1887, Lord Rayleigh (Phil. Mag., 1887, 33, 223) approached very much more nearly than Baur to the zero of magnetic force. Using an unannealed Swedish iron wire, he found that when H was gradually diminished from 0-04 to 0-0004 C.G.S. unit, the ratio of magnetization to magnetizing force remained sensibly constant at 6-4, which may therefore with great probability be assumed to represent the initial value of \(k\) for the specimen in question. Experiments with annealed iron gave less satisfactory results, on account of the slowness with which the metal settled down into a new magnetic state, thus causing a "drift" of the magnetometer needle, which sometimes persisted for several seconds. Apart from this complication, it appeared that I was proportional to H when the value of H was less than 0-02.
The observations of Baur and Rayleigh have been confirmed and discussed by (amongst others) W. Schmidt (Wied. Ann., 1895, 54, 655), who found the limiting values of $k$ to be $7.5$ to $9.5$ for iron, and $11.2$ to $13.5$ for steel, remaining constant up to $H = 65$; by P. Cullmann (Elektrotechn. Z., 1896, 14, 502); and by L. Holborn (Berl. Ber., 1897, p. 95, and Wied. Ann., 1897, 61, 281). The latter gives values of the constants $a$ and $b$ for different samples of iron and steel, some of which are shown in the following table:

For most samples of steel the straight-line law was found to hold approximately up to $H = 3$; in the case of iron and of soft steel the approximation was less close.

The behaviour of nickel in weak fields has been observed by Ewing (Phil. Trans., 1888, 179A, 325), who found that the initial value of $k$ was $1.7$, and that it remained sensibly constant until $H$ had reached a value of about five units. While therefore the initial susceptibility of nickel is less than that of iron and steel, the range of magnetic force within which it is approximately constant is about one hundred times greater. Ewing has also made a careful study (Proc. Roy. Soc., 1888, 56, 269) of “magnetic viscosity” under small forces—the cause of the magnetometer “drift” referred to by Rayleigh. On the application of a small magnetizing force to a bar of soft annealed iron, a certain intensity of magnetization is instantly produced; this, however, does not remain constant, but slowly increases for some seconds or even minutes, and may ultimately attain a value nearly twice as great as that observed immediately after the force was applied. When the magnetizing current is broken, the magnetization at once undergoes considerable diminution, then gradually falls to zero, and a similar sudden change follows by a slow one is observed when a feeble current is reversed. Ewing draws attention to a curious consequence of this time-lag. By the alternate application and withdrawal of a small magnetizing force a cyclic condition may be established in an iron rod. If now the alternations are performed so rapidly that time is not allowed for more than the first sudden change in the magnetization, there will be no hysteresis loss, the magnetization exactly following the magnetizing force. Further, if the alternations take place so slowly that the maximum and minimum values of the magnetization are not between the reversals, there will again be no dissipation of energy. But at any intermediate frequency the ascending and descending curves of magnetization will enclose a space, and energy will be dissipated. It is remarkable that the phenomena of magnetic viscosity are much more evident in a thick rod than in a thin wire, or even in a large bundle of thin wires. In hardened iron and steel the effect can scarcely be detected, and in weak fields these metals exhibit no magnetic hysteresis of any kind.

6. CHANGES OF DIMENSIONS ATTENDING MAGNETIZATION

It is well known that the form of a piece of ferromagnetic metal is in general slightly changed by magnetization. The phenomenon was first noticed by J. P. Joule, who in 1842 and 1847 described some experiments which he had made upon bars of iron and steel. His observations were for the most part confirmed by a number of subsequent workers, notably by A. Mayer; but with the single exception of the discovery by W. F. Barrett in 1882 that a nickel bar contracts when magnetized, nothing of importance was added by Joule’s results for nearly forty years. Later researches have however thrown much new light upon a class of phenomena which cannot fail to have an important bearing upon the complete theory of molecular magnetism. According to Joule’s observations, the length of a bar of iron or soft steel was increased by magnetization, the elongation being proportional up to a certain point to the square of the intensity of magnetization; but when the “saturation point” was approached the elongation was less than this law would require, and a stage was finally reached at which further increase of the magnetizing force produced little or no effect upon the length. From data contained in Joule’s paper it may be calculated that the strongest external field $H$ produced by his coil was about 126 C.G.S. units; but since the dimensional ratio of his bars was comparatively small, the actual magnetizing force $H$ must have been materially below that value. In 1885 it was shown by Bidwell, in the first of a series of papers on the subject, that if the magnetizing force is pushed beyond the point at which Joule discontinued his experiments, the extension of the bar does not remain unchanged, but becomes gradually less and less, until the bar, after first returning to its original length, ultimately becomes actually shorter than when in the unmagnetized condition. The elongation is generally found to reach a maximum under a magnetizing force of 50 to 120 units, and to vanish under a force of 200 to 400, retraction occurring when still higher forces are applied. In order to meet the objection that the phenomenon might be due to electromagnetic action between the coil and the rod, Bidwell made some experiments with iron rings, and found that the length of their diameters varied under magnetization in precisely the same manner as the length of a straight rod. Experiments were afterwards made with rods of iron, nickel, and cobalt, the external field being carried up to the high value of 1500 units. The results are indicated in Fig. 24. It appears that the contraction which followed the initial extension of the iron reached a limit in fields of 1000 or 1100. Nickel exhibited retraction from the very beginning (as observed by Barrett), its greatest change of length considerably exceeding that undergone by iron; in a field of 800 the original length was diminished by as much as $1/40,000$ part, but stronger forces failed to produce any further effect. The curve for cobalt is a very remarkable one. Little or no change of length was observed until the retraction of the field $H$ reached about 30; then the bar began to contract, and after passing a minimum at $H = 400$, recovered its original length at $H = 750$; beyond this point there was extension, the amount of which was still increasing fast when the experiment was stopped at $H = 1400$. Similar results were obtained with three different samples of the metal. Roughly speaking, therefore, cobalt behaves oppositely to iron.

Joule and others experimented with hardened steel, but failed to find a key to the results they obtained, which are rather complex, and have been thought to be inconsistent. The truth appears to be that a hardened steel rod generally behaves like one of iron or soft steel in first undergoing extension under increasing magnetizing force, and recovering its original length when the force has reached a certain critical value, beyond which there is contraction. But this "critical value" of the force is found to depend in an unexpected manner upon the hardness of the steel; the critical value diminishes as the hardness becomes greater up to a certain point, corresponding to a yellow temper, after which it increases and with the hardest steel becomes very high. For steel which has been made red-hot, suddenly cooled, and then let down to a yellow temper, the critical value of the magnetizing force is smaller than for steel which is either softer or harder; it is indeed so small that the metal contracts like nickel even under weak magnetizing forces, without undergoing any preliminary extension that can be detected.

Joule also made experiments upon iron wires under tension, and drew the erroneous inference (which has been often quoted as if it were a demonstrated fact) that under a certain critical tension (differing for different specimens of iron but independent of the magnetizing force) magnetization would produce no effect whatever upon the dimensions of the wire. What actually happens when an iron wire is loaded with various weights is clearly shown in Fig. 25. Increased tension merely has the effect of diminishing the maximum elongation and hastening the contraction; with the two greatest loads used in the experiment there was indeed no preliminary extension at all. The effects of tension upon the behaviour of a nickel wire are of a less simple character. In weak fields the magnetic contraction is always diminished by pulling stress; in strong fields the contraction increases under a small load and diminishes under a heavy one. Cobalt, curiously enough, was found to be quite unaffected by tensile stress.

Certain experiments by C. G. Knott on magnetic twist, which will be referred to later, led him to form the conclusion that in an iron wire carrying an electric current the magnetic elongation would be increased. This forecast was shown by Bidwell to be well founded. The effect produced by a current is exactly opposite to that of tension, raising the elongation curve instead of depressing it. In the case of a wire 0.75 mm. in diameter the maximum elongation was nearly doubled when a current of two amperes was passing through the iron, while the "critical value" of the field was increased from 130 to 200. Yet notwithstanding this enormous effect in iron, the action of a current upon nickel and cobalt turned out to be almost inappreciable.

Some experiments were next undertaken with the view of ascertaining how far magnetic changes of length in iron were dependent upon the hardness of the metal, and the unexpected result was arrived at that softening produces the same effect as tensile stress; it depresses the elongation curve, diminishing the maximum extension, and reducing the "critical value" of the magnetizing force. A thoroughly well annealed ring of soft iron indeed showed no extension at all, beginning to contract, like nickel, under the smallest magnetizing forces. The experiments were not sufficiently numerous to indicate whether, as is possible, there is a critical degree of hardness for which the height of the elongation curve is a maximum.

Finally, experiments were made to ascertain the effect of magnetization upon the dimensions of iron rings in directions perpendicular to the magnetization, and upon the volume of the rings. It was found that the curve showing the relation of transverse changes of dimensions to magnetizing force was similar in general character to the familiar elongation curves, but the signs were reversed; the curve was inverted, indicating at first retraction, which, after passing a maximum and vanishing in a critical field, was succeeded by elongation. The curve showing the circumferential (or longitudinal) changes was also plotted, and from the two curves thus obtained it was easy, on the assumption that the metal was isotropic in directions at right angles to the magnetization, to calculate changes of volume; for if circumferential elongation be denoted by \( h_1 \) and transverse elongation by \( h_2 \), then the cubical dilatation (+ or -) \( h_1 + h_2 \) approximately. If \( h_1 \) were exactly equal to \( -2h_2 \) for all values of the magnetizing force, it is clear that the volume of the ring would be unaffected by magnetization. 

In the case of the ring in question, the circumferential changes were in weak fields less than twice as great as the transverse ones, while in strong fields they were more than twice as great; under increasing magnetic force therefore the volume of the ring was first diminished, then it regained its original value and ultimately increased. It was also shown that annealing, which has a very appreciable circumferential (or longitudinal) changes, has almost none upon transverse ones. Hence the changes of volume undergone by a given sample of wrought iron under increasing magnetization must depend largely upon the state of the metal as regards hardness; there may be always contraction, or always expansion, or first one and then the other.

Most of the experiments described above have been repeated and the results confirmed by other workers, some of whom have added fresh observations. The complicated hysteresis effects which attend magnetic elongation and retraction have been studied by H. Nagaoka, who also, in conjunction with K. Honda, measured the changes of length of various metals shaped in the form of ovoids instead of cylindrical rods, and determined the magnetization curves for the same specimens; a higher degree of accuracy was thus attained, and satisfactory data were provided for testing theories. Among other things, it was found that the behaviour of cast cobalt was entirely changed by annealing; the sinusous curve shown in Fig. 24 was converted into a perfectly straight line passing through the origin, and lying below the horizontal axis; while the permeability of the metal was greatly diminished by the operation. They also tested several varieties of nickel-steel in the form of both ovoids and wires. With a sample containing 25% of nickel no appreciable change was detected; others containing larger percentages, and tested in fields up to 2000, all exhibited elongation, which tended to an asymptotic value as the field was increased. The influence of temperature varying between wide limits has formed the subject of a research by K. Honda and S. Shimizu. For soft iron, tungsten-steel and nickel little difference appeared to result from lowering the temperature down to -180° C. (the temperature of liquid air); at sufficiently high temperatures, 600° to 1000° or more, it was remarked that the changes of length in iron, steel and cobalt tended in every case to become proportional to the magnetic force, the curves being nearly straight lines entirely above the axis. The retraction of nickel was diminished by rising temperature, and at 400° had almost disappeared. The high temperature on cobalt was very remarkable, completely altering the character of the curve. The change of length: the curves for annealed cobalt show that at 450° this metal behaves just like iron at ordinary temperatures, lengthening in fields up to about 300 and contracting in stronger ones. The same physicists have made some additional experiments upon the effect of tension on magnetic change of length. Bidwell's results for iron and nickel were confirmed, and it was further shown that the elongation of nickel-steel was very greatly diminished by tension; while

---

1 The loads were successively applied in decreasing order of magnitude. They are indicated in Fig. 25 as kilos per sq. cm.

2 Joule believed that the volume was unchanged.
MAGNETISM

[STRESS AND MAGNETIZATION]

regarded as a "correction" to be applied to the results of experiments on magnetic change of length, the magnetic stress being no less an extraneous effect than a stress applied mechanically. Those who support this view generally speak of the stress as "Maxwell's stress," and assume its value to be $B^2/8\pi$. The stress in question seems, however, to be quite unconnected with the "stress in the medium" contemplated by Maxwell, and its value is not exactly $B^2/8\pi$ except in the particular case of a permanent ring magnet, when $H=0$. Further, Maxwell's stress is a tension along the lines of force, and is equal to $B^2/8\pi$ only when $B=H$, and there is no magnetization. Some writers have indeed contended that the stress in magnetized iron is not compressive, but tensile, even when, as in the case of a ring-magnet, there are no free ends. The point at issue has an important bearing upon the possible correlation of magnetic phenomena, but, though it has given rise to much discussion, no accepted conclusion has yet been reached.

7. EFFECTS OF MECHANICAL STRESS UPON MAGNETIZATION

The effects of traction, compression and torsion in relation to magnetism have formed the subject of much patient investigation, especially at the hands of J. A. Ewing, C. G. Knott and the indefatigable physicists of Tokyo University. The results of their experiments embrace a multiplicity of details of which it is impossible to give an adequate summary. Only a few of the most important can be mentioned here; the reader who wishes for fuller information should consult the original papers.

It was first discovered by E. Villari in 1868 that the magnetic susceptibility of an iron wire was increased by stretching when the magnetization was below a certain value, but diminished when that value was exceeded; this phenomenon has been termed by Lord Kelvin, who discovered it independently, the "Villari reversal," the value of the magnetization for which stretching by a given load produces no effect being known as the "Villari critical point" for that load. The Villari critical point for a given sample of iron is reached with a smaller magnetizing force when the stretching load is great than when it is small; the reversal also occurs with smaller loads and with weaker fields when the iron is soft than when it is hard. The following table shows the values of $I$ and $H$ corresponding to the Villari critical point in some of Ewing's experiments:

The effects of pulling stress may be observed either when the wire is stretched by a constant load while the magnetizing force is varied, or when the magnetizing force is kept constant while the load is varied. In the latter case the first application of stress is always attended by an increase—often a very great one—of the magnetization, whether the field is weak or strong, but after a load has been put on and taken up the stress is no longer capable of producing magnetic change.

From experiments of both classes it appears that for a given load there is a certain value of the load for which the magnetization is a maximum, the maximum occurring at a smaller load than the stronger the field. In very strong fields the maximum may even disappear altogether, the effect of the smallest stress...
being to diminish the magnetization; on the other hand, with very weak fields the maximum may not have been reached with the greatest load that the wire can support without permanent deformation. When the load on a hardened wire is gradually increased, the maximum value of I is found to correspond with a greater stress than when the load is gradually diminished, this being an effect of hysteresis. Analogous changes are observed in the residual magnetization which remains after the wire has been subjected to fields of different strength. The effects of longitudinal pressure are opposite to those of traction; when the cyclic condition has been reached, pressure reduces the magnetization of iron in weak fields and increases it in strong fields (Ewing, *Magnetic Induction*, 1900, 233).

The influence of traction in diminishing the susceptibility of nickel was first noticed by Kelvin (W. Thomson), and was subsequently investigated by Ewing and Cowan. The latter found the effect to be enormous, not only upon the induced magnetization, but in a still greater degree upon the residual. Even under so "moderate" a load as 33 kilograms per square mm., the induced magnetization of a hard-drawn nickel wire in a field of 60 fell from 386 to 72 units, while the residual was diminished from 250 to 0.2. Ewing explained the effects produced by longitudinal compression upon the susceptibility and retentiveness of nickel, and found, as was to be expected, that both were greatly increased by pressure. The maximum susceptibility of one of his bars rose from 5-6 to 29 under a stress of 10-8 kilos per square mm. There were reasons for believing that no Villari reversal would be found in nickel. Ewing and Cowan looked carefully for it, especially in weak fields, but failed to discover anything of the kind.¹

Some experiments by A. Heydweiller,² which appeared to indicate a reversal in weak fields (corresponding to I=5, or thereabouts), have been shown by Honda and Shimizu to be vitiated by the fact that his specimen was not initially in a magnetically neutral state; they found that when the applied field had the same direction as that of the permanent magnetization, Heydweiller's fallacious results were easily obtained; but if the field were applied in the direction opposite to that of the permanent magnetization, or if, as should rightly be the case, there were no permanent magnetization at all, then there was no indication of any Villari reversal. Thus a very important relation, which has given rise to some controversy, appears to be now definitely settled.

The effects of longitudinal pressure upon the magnetization of cast cobalt have been examined by C. Chree,³ and also by J. A. Ewing.⁴ Chree's experiments were undertaken at the suggestion of J. J. Thomson, who, from the results of Bidwell's observations on the magnetic deformation of cobalt, was led to expect that that metal would exhibit a reversal opposite in character to the effect observed in iron. The anticipated reversal was duly found by Chree, the critical point corresponding, under the moderate stress employed, to a field of about 120 units. Ewing's independent experiments showed that the magnetization curve for a cobalt rod under a load of 16-2 kilograms per square mm. crossed the curve for the same rod when not loaded at H=53. Both observers noticed analogous effects in the residual magnetization. The effect of tension was subsequently studied by Nagaoka and Honda, who in 1902 confirmed, *mutatis mutandis*, the results obtained by Chree and Ewing for cast cobalt; while for annealed cobalt it turned out that tension first diminished the magnetization, the diminution increasing with increasing fields. They also investigated the magnetic behaviour of various nickel-steels under tension, and found that there was always increase of magnetization. Thus it has been proved that in annealed cobalt and in nickel-steel there is no Villari reversal.

¹ H. Tomlinson found a critical point in the "temporary magnetization " of nickel (*Proc. Phys. Soc.*, 1890, 10, 367, 445), but this does not correspond to a Villari reversal. Its nature is made clear by Ewing and Cowan's curves (Phil. *Trans.*, 1888, 179, plates 15, 16).

⁴ *Magnetic Induction*, 1900, 222.

### Magnetism

It has been pointed out by J. J. Thomson (*Applications of Dynamics to Physics and Chemistry*, 47) that on dynamical principles there must be a reciprocal relation between the changes of dimensions produced by magnetization and the changes of magnetization attending mechanical strain. Since, for example, stretching diminishes the magnetization of nickel, it follows from theory that the length of a nickel rod should be diminished by magnetization and conversely. So, too, the Villari reversals in iron and cobalt might have been predicted—as indeed that in cobalt actually was—from a knowledge of the changes of length which those metals exhibit when magnetized.

The complete reciprocity of the effects of magnetization upon length and of stretching upon magnetization is shown by the following parallel statements:

**Iron.**

- Magnetization produces increase of length in weak fields, magnetization in weak fields, decrease in strong fields.
- Cast Cobalt.
- Magnetization produces decrease of length in weak fields, increase in strong fields.
- Nickel and Annealed Nickel.
- Magnetization produces decrease of length in all fields.
- Nickel-Steel.
- Magnetization produces increase of length in all fields.

Nagaoka and Honda (*Phil. Mag.*, 1898, 46, 261) have investigated the effects of hydrostatic pressure upon magnetization, using the same pieces of iron and nickel as were employed in their experiments upon magnetic change of volume. In the iron cylinder and ovoid, which expanded when magnetized, compression caused a diminution of magnetization; in the nickel rod, which contracted when magnetized, the pressure was attended by an increase of magnetization. The amount of the change was in both cases exceedingly small, that in iron being less than 0-1 C.G.S. unit with a pressure of 250 atmospheres and H=54. It would hardly be safe to generalize from these observations; the results may possibly depend upon the physical condition of the metals. In the same paper Nagaoka and Honda describe an important experiment on the effect of transverse stress. An iron tube, having its ends closed by brass caps, was placed inside a compressing vessel into which water was forced until the pressure upon the outer surface of the tube reached 250 atmospheres. The experiment was the reverse of one made by Kelvin with a gun-barrel subjected to internal hydrostatic pressure (*Phil. Trans.*, 1878, 152, 613) in which, it was shown that the magnetizing force the magnetization first increased, reached a maximum, and then diminished until its value ultimately became less than when the iron was in the unstrained condition. Experiments on the effect of external hydrostatic pressure upon the magnetization of iron rings have also been made by F. Frisbie,⁵ who found that for the magnetizing forces used by Nagaoka and Honda pressure produced a small increase of magnetization, a result which appears to be in accord with theory.

The relations of torsion to magnetization were first carefully studied by G. Wiedemann, whose researches are described in his *Elektricität*, iii. 671. The most interesting of his discoveries, now generally known as the "Wiedemann effect," is the following: If we magnetize longitudinally a straight wire which is fixed at one end and free at the other, and then pass an electric current through the wire (which will then magnetize); the free end of the wire will twist in a certain direction depending upon circumstances: if the wire is of iron, and is magnetized (with a moderate force) so that its free end has north polarity, while the current through it passes from the fixed to the free end, then the free end as seen from the fixed end will twist in the direction of the hands of a watch; if either the magnetization or the current is reversed, the direction of the twist will be reversed. To this mechanical phenomenon there is a magnetic reciprocal. If we twist the free end of a ferromagnetic wire while a current is passing through it, the wire becomes longitudinally magnetized, the direction of the magnetization depending upon circumstances: if the wire is of iron and is twisted so that its free end as seen from the fixed end turns in the direction of the hands of a watch, while

⁵ *Phys. Rev.*, 1904, 18, 432.
the current passes from the fixed to the free end, then the direction of the resulting magnetization will be such as to make the free end a north pole. The twist effect exhibited by iron under moderate longitudinal magnetization has been called by Knott a positive Wiedemann effect; if the twist were reversed, the other conditions remaining the same, the sign of the Wiedemann effect would be negative. An explanation of the twist has been given by Maxwell (Electricity and Magnetism, § 448). The wire is subject to two superposed magnetizations, the one longitudinal, the other circular, due to the current traversing the wire; the resultant magnetization is consequently in the direction of a screw or spiral round the wire, which will be right-handed or left-handed according as the relation between the two magnetizations is right-handed or left-handed; the magnetic expansion or contraction of the metal along the spiral lines of magnetization produces the Wiedemann twist. Iron (moderately magnetized) expands along the lines of magnetization, and therefore for a right-handed spiral exhibits a right-handed twist. This explanation was not accepted by Wiedemann, who thought that the effect was accounted for by molecular friction. Now nickel contracts instead of lengthening when it is magnetized, and an experiment by Knott showed, as he expected, that caeteris paribus a nickel wire twists in a sense opposite to that in which iron twists. The Wiedemann effect being positive for iron is negative for nickel. Further, although iron lengthens in fields of moderate strength, it contracts in strong ones; and if the wire is stretched, contraction occurs with smaller magnetizing forces than if it is unstretched. Bidwell 1 accordingly found upon trial that the Wiedemann twist of an iron wire vanished when the magnetizing force reached a certain high value, and was reversed when that value was exceeded; he also found that the vanishing point was reached with lower values of the magnetizing force when the wire was stretched by a weight. These observations have been verified and extended by Knott, whose researches have brought to light a large number of additional facts, all of which are in perfect harmony with Maxwell's explanation of the twist.

Maxwell has also given an explanation of the converse effect, namely, the production of longitudinal magnetization by twisting a wire when circularly magnetized by a current passing through it. When the wire is free from twist, the magnetization at any point \( P \) is in the tangential direction \( PB \) (see fig. 26). Suppose the wire to be fixed at the top and twisted at the bottom in the direction of the arrow-head \( T \); then the element of the wire at \( P \) will be stretched in the direction \( PE \) and compressed in the direction \( PR \). But tension and compression produce opposite changes in the magnetic susceptibility; if the metal is iron and its magnetization is below the Villari critical point, its susceptibility will be greater along \( PE \) than along \( PR \); the direction of the magnetization therefore tends to approach \( PE \) and to recede from \( PR \), changing, in consequence of the twist, from \( PB \) to some such direction as \( PB' \), which has a vertical component downwards; hence the lower and upper ends will respectively acquire north and south polarity, which will disappear when the wire is untwisted. This effect has never been actually reversed in iron, probably, as suggested by Ewing, because the strongest practicable circular fields fail to raise the components of the magnetization along \( PE \) and \( PR \) up to the Villari critical value. Nagaoka and Honda have approached very closely to a reversal, and consider that it would occur if a sufficiently strong current could be applied without undue heating.

One other effect of torsion remains to be noticed. If a longitudinally magnetized wire is twisted, circular magnetization is developed; this is evidenced by the transient electromotive force induced in the iron, generating a current which will deflect a galvanometer connected with the two ends of the wire. The explanation given of the last described phenomenon will with the necessary modification apply also to this; it is a consequence of the aclotropy produced by the twist. There are then three remarkable effects of torsion:

A. A wire magnetized longitudinally and circularly becomes twisted.

B. Twisting a circularly magnetized wire produces longitudinal magnetization.

C. Twisting a longitudinally magnetized wire produces circular magnetization.

And it has been shown earlier that—

D. Magnetization produces change of length.

E. Longitudinal stress produces change of magnetization.

Each of these five effects may occur in two opposite senses. Thus in A the twist may be right-handed or left-handed; in B the polarity of a given end may become north or south; in C the circular magnetization may be clockwise or counter-clockwise; in D the length may be increased or diminished; in E the magnetization may become stronger or weaker. And, other conditions remaining unaltered, the "sense" of any effect depends upon the nature of the metal under test, and (sometimes) upon the intensity of its magnetization. Let each of the effects A, B, C, D and E be called positive when it is such as is exhibited by moderately magnetized iron, and negative when its sense is opposite. Then the results of a large number of investigations may be briefly summarized as follows:

\[
(W) = \text{weakly magnetized.} \\
(S) = \text{strongly magnetized.} \\
\text{Metal.} \\
\text{Effects.} \\
\text{Sign.} \\
\text{Iron (W)} & A, & B, & C, & D, & E, & + \\
\text{Nickel-steel (W)} & A, & D, & E, & + \\
\text{Nickel} & A, & B, & C, & E, & - \\
\text{Annealed Cobalt} & A, & C, & D, & E, & + \\
\text{Unannealed Cobalt} & A, & D, & E, & - \\
\]

Several gaps remain to be filled, but the results so far recorded can leave no doubt that the five effects, varied as they may at first sight appear, are intimately connected with one another. For each of the metals tabulated in the first column all the effects hitherto observed have the same sign; there is no single instance in which some are positive and others negative. Until the mysteries of molecular constitution have been more fully explored, perhaps D may be most properly regarded as the fundamental phenomenon from which the others follow. Nagaoka and Honda have succeeded in showing that the observed relations between twist and magnetization are in qualitative agreement with an extension of Kirchhoff's theory of magnetostriction.

The effects of magnetization upon the torsion of a previously twisted wire, which were first noticed by Wiedemann, have been further studied by F. J. Smith 2 and by G. Moreau. 3 Nagaoka 4 has described the remarkable influence of combined torsion and tension upon the magnetic susceptibility of nickel, and has made the extraordinary observation that, under certain conditions of stress, the magnetization of a nickel wire may have a direction opposite to that of the magnetizing force.

8. Effects of Temperature upon Magnetism

High Temperature.—It has long been known that iron, when raised to a certain "critical temperature" corresponding to dull red heat, loses its susceptibility and becomes magnetically indifferent, or, more accurately, is transformed from a ferromagnetic into a paramagnetic body. Recent researches have shown that other important changes in its properties occur at the same critical temperature. Abrupt alterations take place in its density, specific heat, thermo-electric quality, electrical conductivity, temperature-coefficient of electrical resistance, and in some at least of its mechanical properties. Ordinary magnetizable iron is in many respects an essentially different substance from the non-magnetizable metal into which it is transformed when its temperature is raised above a certain point (see Brit. Assoc. Report, 1890, 145). The first exact experiments demonstrating the changes which occur in the permeability of iron,

1 Phil. Mag., 1891, 32, 383.
2 C.R., 1896, 122, 1192; 1898, 126, 463.
3 Phil. Mag., 1889, 27, 117.
steel and nickel when heated up to high temperatures were those of J. Hopkinson (Phil. Trans., 1889, 180, 443; Proc. Roy. Soc., 1888, 44, 271). The metal to be tested was prepared in the form of a ring, upon which were wound primary and secondary coils of copper wire insulated with asbestos. The primary coil carried the magnetizing current; the secondary, which was wound inside the other, could be connected either with a ballistic galvanometer for determining the induction, or with a Wheatstone's bridge for measuring the resistance, whence the temperature was calculated. The ring thus prepared was placed in a cast-iron box and heated in a gas furnace. The following are the chief results of Hopkinson's experiments: For small magnetizing forces the magnetization of iron steadily increases with rise of temperature till the critical temperature is approached, when the rate of increase becomes very high, the permeability in some cases attaining a value of about 11,000; the magnetization then with remarkable suddenness almost entirely disappears, the permeability falling to about 1-14. For strong magnetizing forces (which in these experiments did not exceed $H = 45-9$) the permeability remains almost constant at its initial value (about 400), until the temperature is raised within nearly 100° of the critical point; then the permeability diminishes more and more rapidly until the critical point is reached and the magnetization vanishes. Steel behaves in a similar manner, but the maximum permeability is not so high as in iron, and the fall, when the critical point is approached, is less abrupt. The critical temperature for various samples of iron and steel ranges from 690° C. to 870° C.; it is the temperature at which Barrett's "recalescence" occurs. The critical temperature for the specimen of nickel examined (which contained nearly 5% of impurities) was 310° C. F. Lydall and A. W. Pocklington found that the critical temperature of nearly pure iron was 874° C. (Roy. Soc. Proc., 1893, 52, 228).

An exhaustive research into the effects of heating on the magnetic properties of iron has been carried out by D. K. Morris (Proc. Phys. Soc., 1897, 15, 134; and Phil. Mag., 1897, 44, 213), the results being embodied in a paper containing twelve pages of tables and upwards of 120 curves. As in Hopkinson's experiments, rings of magnet were employed; these were wound with primary and secondary coils of insulated platinum wire, which would bear a much higher temperature than copper without oxidation or fusion. A third platinum coil, wound non-inductively between the primary and the secondary, served to carry the current by which the ring was heated; a current of 4-6 amperes, with 16 volts across the terminals, was found sufficient to maintain the ring at a temperature of 1150° C. In the ring itself was embedded a platinum-thermometer wire, from the resistance of which the temperature was determined. The whole was wrapped in several coverings of asbestos and placed in a glass vessel from which the air was partially exhausted, additional precautions being taken to guard against oxidation of the iron.

Some preliminary experiments showed the striking difference in the effects of annealing at a red heat (840° C.) and at a low white heat (1150° C.). After one of the rings had been annealed at 840°, its maximum permeability at ordinary temperatures was 4500 for $H = 1.84$; when it had been successively annealed at 1150°, the maximum permeability rose to 4500 for $H = 1.14$, while the hysteresis loss for $B = 4000$ was under 500 ergs per c.cm. As regards the effects of cooling and heating, Morin's results are in general agreement with those of Hopkinson, though no doubt they indicate details with greater clearness and accuracy. Specimens of curves showing the relation of induction to magnetic field at various temperatures, and of permeability to temperature with fields of different intensities, are given in figs. 27 and 28. The most striking feature presented by these is the enormous value, 12,660, which, with $H = 0.133$, is attained by the permeability at 765° C., followed by a drop so precipitous that when the temperature is only 15° higher, the value of the permeability has become quite insignificant. The critical temperatures for three different specimens of iron were 795, 790 and 790° C. Above these temperatures the little permeability that remained was found to be independent of the magnetizing force, but it appeared to vary a little with the temperature, one specimen showing a permeability of 100 at 820°, 2-3 at 950°, and 17 at 1050°. These last observations are, however, regarded as uncertain. The effects of temperature upon hysteresis were also carefully studied, and many hysteresis loops were plotted. The results of a typical experiment are given in the annexed table, which shows how greatly the hysteresis loss is diminished as the critical temperature is approached. The coercive force at 764.5° is also shown to have been reduced to less than 0.1 C.G.S. unit; above the critical temperature no evidence of hysteresis could be obtained.

Hysteresis Loss in Ergs per c.cm. Max. H. = 6-83.

354 1345

A paper by H. Nagaoka and S. Kusaka1 generally confirms Morris's results for iron, and gives some additional observations for steel, nickel and cobalt. The magnetometric method was employed, and the metals, in the form of ovoids, were heated by a specially designed burner, fed with gas and air under pressure, which directed a blast of flame upon the asbestos covering the ovoid. The temperature was determined by a platinum-iodium and platinum thermo-junction in contact with the metal. Experiments were made at several constant temperatures with varying magnetic fields, and the results are plotted in the attached figure. For ordinary steel the critical temperature, at which magnetization practically disappeared, was found to be about 830°, and the curious fact was revealed that, on cooling, magnetization did not begin to appear until the temperature had sunk 40° below the critical value. This retardation was still more pronounced in the case of tungsten-steel, which lost its magnetism at 910° and remained non-magnetic till it was cooled to 570°, a difference of 240°. For nearly pure nickel the corresponding temperature-difference was about 100°. This phenomenon is of the same nature as that first discovered by J. Hopkinson for nickel-steel. The paper contains tables and curves showing details of the magnetic changes, sometimes very complex, at different temperatures and with different fields. The behaviour of cobalt is particularly noticeable; its permeability increased with rising temperature up to a maximum at 500°, when it was about twice as great as at ordinary temperatures, while at 1600°, corresponding to white heat, there was still some magnetism remaining.

Further contributions to the subject have been made by K. Honda and S. Shimizu,2 who experimented at temperatures ranging from -186° to 1200°. As regards the higher temperatures, the chief point of interest is the fact that the curve of magnetization for annealed cobalt shows a small depression at about 450°, the temperature at which they had found the sign of the length-change to be reversed for all fields. In the case of all the metals tested a small but measurable trace of magnetization remained after the so-called critical temperature had been exceeded; this decreased very slightly up to the highest temperature reached (1200°) without undergoing any such variation as had been suspected by Morris. When the curve after its steep descent has almost reached the axis, it bends and falls sharply and becomes a nearly horizontal straight line; the authors suggest that the critical temperature should be defined as that corresponding to the point of maximum curvature. As thus defined the critical temperatures for iron, nickel and cobalt were

---

MAGNETISM

TEMPERATURE AND MAGNETIZATION

found to be 78°, 360° and 1090° respectively, but these values are not quite independent of the magnetizing force.

Experiments on the effect of high temperatures have also been made by M. F. Ledeboer, H. Tomlison, F. Cutie, and W. Wunz, R. L. Willis, J. R. Ashworth and E. P. Harrison.

Low Temperature.—J. A. Fleming and J. Dewar (Proc. Roy. Soc., 1896, 60, 81) were the first to experiment on the permeability and hysteresis of iron at low temperatures down to that of liquid air (−186°C). Induction curves of an annealed soft-iron ring were taken first at a temperature of 15°C, and afterwards when the ring was immersed in liquid air, the magnetizing force ranging from about 0 to 22. After this operation had been repeated a few times the iron was found to have acquired a stable condition, and the curves corresponding to the two temperatures became perfectly definite. They showed that the permeability of this sample of iron was considerably diminished at the lower temperature. The maximum permeability (for H = 2) was 3400 at 15°C and only 2700 at −186°C, a reduction of more than 20%; but the percentage reduction became less as the magnetizing force departed from the value corresponding to maximum permeability. Observations were also made of the changes of permeability which took place as the temperature of the sample slowly rose from −186°C to 15°C, the magnetizing force being kept constant throughout an experiment. The results, together with the conditions and the lowest temperatures are given in the following table. Most of the permeability-temperature curves were more or less convex towards the axis of temperature, and in all the experiments, except those with annealed iron and steel wire, the permeability was greatest at the lowest temperature. The hysteresis of the soft annealed iron turned out to be sensibly the same for equal values of the induction at −186°C as at 15°C, the loss in ergs per c.c.m. per cycle being approximately represented by 0.002 B² when the maximum limits of B were ± 9000. Experiments with the sample of unannealed iron failed to give satisfactory results, owing to the fact that no constant magnetic condition could be obtained.

Honda and Shimizu have made similar experiments at the temperature of liquid air, employing a much wider range of magnetizing forces (up to 700 C.G.S.) and testing a greater variety of metals. They found that the permeability of Swedish iron, tungsten-steel and nickel, when the metals were cooled to −186°C, was diminished in weak fields but increased in strong ones, the field in which the effect of cooling changed its sign being 115 for iron and steel and 880 for nickel. The permeability of cobalt, both annealed and unannealed, was always diminished at the low temperature. The hysteresis-loss in Swedish iron was decreased for inductions below about 50 ergs per c.cm. for higher inductions; in tungsten-steel nickel and cobalt the hysteresis-loss was always increased by cooling. The range of ± B within which Steinmetz's formula is applicable becomes not absolutely increased at low temperature. It may be remarked that, when Fleming and Dewar employed the ballistic method, their specimens having the form of rings, Honda and Shimizu worked magnetometrically with metals shaped as ovoids.

Permanent Magnets.—Fleming and Dewar (loc. cit. p. 57) also investigated the changes which occurred in permanently magnetized metals when cooled to the temperature of liquid air. The metals, which were prepared in the form of small rods, were magnetized between the poles of an electromagnet and tested with a magnetometer at temperatures of −186°C and 15°C. The first immersion in liquid air generally produced a permanent decrease of magnetic moment, and there was sometimes a further decrease when the metal was warmed up again; but after a few alternations of temperature the changes of moment became definite and cyclic. When the permanent magnetic condition had been thus established, it was found that in the case of all the metals, except the two alloys containing large percentages of nickel, the magnetic moment was temporarily increased by cooling to −186°C. The following table shows the principal results. It is suggested that a permanent magnet might conveniently be aged (or brought into a constant condition) by dipping it several times into liquid air.

Other experiments relating to the effect of temperature upon permanent magnets have been carried out by J. R. Ashworth, who showed that the temperature coefficient of permanent magnets might be reduced to zero (for moderate ranges of temperature) by suitable adjustment of temper and dimension ratio; also by R. Picket, W. J. Ashworth and E. P. Harrison.

Alloys of Nickel and Iron.—A most remarkable effect of temperature was discovered by Hopkinson (Proc. Roy. Soc., 1890, 97, 23; 1891, 48, 1) in 1889. An alloy containing about 3 parts of iron and 1 of nickel—both strongly magnetic metals—is under ordinary conditions practically non-magnetizable (μ=1.4 for any value of H). If, however, this non-magnetic substance is cooled to a temperature a few degrees below freezing-point, it becomes as strongly magnetic as average cast-iron (μ=62 for H=40), and retains its magnetic properties indefinitely at ordinary temperatures. But if the alloy is heated up to 589°C it loses its susceptibility—rather suddenly when H is weak, more gradually when H is strong—and remains non-magnetizable till it is once more cooled down below the freezing-point. This material can therefore exist in either of two perfectly stable conditions, in one of which it is magnetizable, while in the other it is not. When magnetizable it is a hard steel, having a specific electrical resistance of 0.000052; when non-magnetizable it is an extremely soft, mild steel, and its specific resistance is 0.000072. Alloys containing different proportions of nickel were found to exhibit the phenomenon, but the two critical temperatures were less widely separated. The following approximate figures for small magnetizing forces are deduced from Hopkinson's curves:

Honda and Shimizu (loc. cit.) have determined the two critical temperatures for eleven nickel-steel alloys, containing from 24.0 to 70.3% of nickel, under a magnetizing force of 400, and illustrated by an interesting series of curves, the gradual transformation of the materials, and the percentage of nickel was decreased. They found that the hysteresis-loss, which at ordinary temperatures is very small, was increased in liquid air, the increase for the alloys containing less than 30% of nickel being enormous. Steinmetz’s formula applies only for very weak inductions when the amperes were at the ordinary temperature, but at the temperature of liquid air it becomes applicable through a wide range of inductions. According to C. E. Guillaume the temperature at which the magnetic susceptibility of iron alloy is rendered by the presence of chromium; a certain alloy containing chromium was not rendered magnetic even by immersion in liquid air. Experiments on the subject have also been made by E. Dumont and F. Osmond.

9. ALLOYS AND COMPOUNDS OF IRON

In 1885 Hopkinson (Phil. Trans., 1885, 176, 455) employed his yoke method to test the magnetic properties of thirty-five samples of iron and steel, among which were steels containing substantial proportions of manganese, silicon, chromium and tungsten. The results, together with the chemical analysis of each sample, are given in a table contained in this paper, some of them being also represented graphically. The most striking phenomenon which they bring into prominence is the effect of any considerable quantity of manganese in annihilating the magnetic property of iron. A sample of Hadfield’s manufacture, containing 12.36% of manganese, differed hardly at all from a non-magnetic substance, its permeability being only 1.27. According to Hopkinson’s calculation, this sample behaved as if 91% of the iron contained in it had completely lost its magnetic property. Another point to which attention is directed is the exceptionally great effect which hardening has upon the magnetic properties of iron. Several specimens had a coercive force of 0.98 when annealed, and of no less than 38 when hardened. The effect of the addition of tungsten in increasing the coercive force is very clearly shown; in two specimens containing respectively 3.44 and 2.25% of tungsten the coercive force was 64.5 and 70.7. These high values render hardened tungsten-steel particularly suitable for the manufacture of permanent magnets. Hopkinson (Proc. Roy. Soc., 1890, 48, 1) also noticed some peculiarities of an unexpected nature in the magnetic properties of the nickel-steel alloys already referred to. The permeability of the alloys containing iron 1 to 4.7% of nickel, though less than that of good soft iron for magnetizing forces up to about 20 or 30, was greater for higher forces, the induction reached in a field of 240 being nearly 21,700. The induction for considerable forces was found to be greater in a steel containing 73% of nickel than in one with only 33%, though the permeability of pure nickel is much less than that of iron.

The magnetic qualities of various alloys of iron have been submitted to a very complete examination by W. F. Barrett, W. Brown and R. A. Hadfield (Trans. Roy. Inst. Soc., 1900, 7, 67; Journ. Inst. Elec. Eng., 1902, 31, 674). More than fifty different specimens were tested, most of which contained a known proportion of manganese, nickel, tungsten, aluminum, chromium, copper or silicon; in some samples two or the substances named were present. Of the very numerous results published, a few of the most characteristic are collected in the following table. The first column contains the symbols of the various elements which were added to the iron, and the second the proportion in which each element was present; the sample containing 0.03% of carbon was a specimen of the best commercial iron, the values obtained for it being given for comparison. All the metals were annealed.

A few among several interesting points should be specially noticed. The addition of 15.2% of manganese produced an enormous effect upon the magnetism of iron, while the presence of only 2.26% was comparatively unimportant. When nickel was added to the iron in increasing quantities the coercive force increased until the proportion of nickel reached 20%, then it diminished, and when the proportion of nickel was 32.4% the coercive force had fallen to the exceedingly low value of 0.5. In the case of iron containing 7.5% of tungsten

(W), the residual induction had a remarkably high value; the coercive force, however, was not very great. The addition of silicon in small quantities considerably diminished permeability and increased coercive force, but the proportion of amperes which produced maximum permeability (\(\mu = 5100\) for \(H = 2\)) was greater than that of the pure iron used for comparison, while the coercive force was only 0.7. A small percentage of aluminium produced still higher permeability, and iron containing 1.0% aluminium was found to be of greater than any other known substance, and the hysteresis-loss for moderate limits of B far less than in the purest commercial iron. Certain non-magnetizable alloys of nickel, chromium-nickel and iron were rendered magnetizable by annealing.

Later papers give the results of a more minute examination of those specimens which were remarkable for very low and very high permeabilities, and were therefore likely to be of commercial importance. The following table gives the exact composition of some alloys which were found to be non-magnetizable, or nearly so, in a field of 320.

A very small difference in the constitution often produces a remarkable effect upon the magnetic quality, and it unfortunately happens that those alloys which are hardest magnetically are generally also hardest mechanically and extremely difficult to work; they might however be used rolled or cast. The specimens distinguished by unusually high permeability were constituted as follows:

**Silicon-iron.** Fe, 97.5; C, 0.2; Si, 2.5

**Aluminium-iron.** Fe, 97.5; C, 0.18; Al, 2.25

The silicon-iron had, in fields up to about 10, a greater permeability than a sample of the best American charcoal-iron, and its hysteresis-loss for max. \(B = 9000\), at a frequency of 100 per second, was only 0.254 watt per pound, as compared with 0.382 for the Swedish iron. The aluminium-iron attained its greatest permeability in a field of 4500, about that of the earth’s field, when its value was 99.9, this being more than twice the maximum permeability of the Swedish iron. Its hysteresis-loss for \(B = 9000\) was 0.236 per pound. It was, however, found that the behavior of this alloy was in part due to a layer of the iron ("ferrite") averaging 0.1 mm. in thickness, which occurred on the outside of the specimen and which the permeability and magnetic quality which has been claimed for aluminium-iron cannot yet be regarded as established.

A number of iron alloys have been examined by Mme. Curie (Bull. Soc. d’Encouragement, 1898, pp. 35–76), chiefly with the object of determining their suitability for the construction of permanent magnets. Her tests appear to show that molybdenum is even more effective than tungsten in augmenting the coercive force, the highest values observed being 70 to 74 for tungsten-steel, and 80 to 85 for steel containing 3.5 to 4.0% of molybdenum. For additional information regarding the composition and qualities of permanent magnet steels reference may be made

The marked effect of silicon in increasing the permeability of cast iron has also been noticed by F. C. Caldwell, Elect. World, 1898, 33, 619, which is applicable to the figures which, through an error, were inaccurately stated in the first paper are corrected in the second.
to the publications cited below. Useful instructions have been furnished by Carl Barus (Terrestrial Magnetism, 1897, 2, 11) for the preparation of magnets calculated to withstand the effects of time, percussion and ordinary temperature variations. The metal, having first been uniformly tempered hard, should be annealed in steam at 100° C. for twenty or thirty hours; it should then be magnetized to saturation, and finally "aged" by a second immersion in steam for about five hours. 

**Magnetic Alloys of Non-Magnetic Metals.**—The interesting discovery was made by F. Heusler in 1903 that certain alloys of the non-magnetic metal manganese with other non-magnetic substances were strongly magnetizable, their susceptibility being in some cases equal to that of cast iron. The metals used in different combinations included tin, aluminium, arsenic, antimony, bismuth and boron; each of these, when united in certain proportions with manganese, together with a larger quantity of copper (which appears to serve merely as a matrix), constituted a magnetizable alloy. So far, the best results have been attained with aluminium, and the permeability was greatest when the percentages of manganese and aluminium were approximately proportional to the atomic weights of the two metals. Thus in an alloy containing 26.5% of manganese and 14.5% of aluminium, the rest being copper, the induction for $H=20$ was 4500, and for $H=150$, 5500. When the proportion of aluminium to manganese was made a little greater or smaller, the permeability was diminished. Next to aluminium, tin was found to be the most effective of the metals enumerated above. In all such magnetizable alloys the presence of manganese appears to be essential, and there may be little doubt that the magnetic quality of the mixtures is derived solely from this component. Manganese, though belonging (with chromium) to the iron group of metals, is commonly classed as a paramagnetic, its susceptibility being very small in comparison with that of the recognized ferromagnetics; but it is remarkable that its atomic susceptibility in solutions of its salts is even greater than that of iron. Now iron, nickel and cobalt all lose their magnetic quality when heated above certain critical temperatures which vary greatly for the three metals, and it was suspected by Faraday as early as 1845 that manganese might really be a ferromagnetic metal having a critical temperature much below the ordinary temperature of the air. He therefore cooled a piece of the metal to $-105$° C., the lowest temperature then attainable, but failed to produce any change in its magnetic quality. The critical temperature (if there is one) was not reached in Faraday's experiment; possibly even the temperature of $-250$° C., which by the use of liquid hydrogen has now become accessible, might still be too high. But it has been shown that the critical temperatures of iron and nickel may be changed by the addition of certain other substances. Generally they are lowered, sometimes, however, they are raised; and C. E. Guillaume explains the ferromagnetism of Heusler's alloy by supposing that the naturally low critical temperature of the manganese contained in it is greatly raised by the admixture of another appropriate metal, such as aluminium or tin; thus the alloy as a whole becomes magnetizable at the ordinary temperature. If this view is correct, it may also be possible to prepare magnetic alloys of chromium, the only other paramagnetic metals of the iron group.

J. A. Fleming and R. A. Hadfield have made very careful experiments on an alloy containing 22-42% of manganese, 11-65% of aluminium and 60-49% of copper. The magnetization curve was found to be of the same general form as that of a paramagnetic metal, and gave indications that with a sufficient force magnetic saturation would probably be attained. There was considerable hysteresis, the energy per cycle being fairly represented by $W=0.0005495H^2+531$. The hysteresis exponent is therefore much higher than in the case of iron, nickel and cobalt, for which its value is approximately 1-6.

**10. Miscellaneous Effects of Magnetization**

**Electrical Conductivity.**—The specific resistance of many electric conductors is known to be temporarily changed by the action of a magnetic field, but except in the case of bismuth the effect is very small.

A. Gray and E. Taylor Jones (Proc. Roy. Soc., 1900, 67, 207) found that the resistance of some iron increased by about 1/700 in a field of 320 G.S. units. The effect appeared to be closely connected with the intensity of magnetization, being approximately proportional to $I$. G. Barlow (Proc. Roy. Soc., 1903, 71, 30), experimenting with wires of iron, steel and nickel, showed that in weak fields the change of resistance was proportional to a function $aH^2+bH+c'$, where $a$, $b$ and $c$ are constants for each specimen. W. E. Williams (Phil. Mag., 1902, 4, 430) found that for nickel the curves showing changes of resistance related to magnetizing force were strikingly in form to those showing changes of H. Tomlinson (Phil. Trans., 1883, Part I, 153) discovered in 1881 that the resistance of a bismuth rod was slightly increased when the rod was subjected to longitudinal magnetic force, and a year or two later A. Righi (Atti. R., 1885, 15, 543) found that considerable alteration was produced when the magnetic force was applied transversely to the bismuth conductor; he also noticed that the effect was largely dependent upon temperature (see also P. Lenard, Hist. Am., 1901, 80, 19). Observations on the influence of magnetic force at different temperatures are those of J. B. Henderson and of Dewar and Fleming. Henderson (Phil. Mag., 1894, 38, 488) used a little spiral of the pure electrolytic platinum, where the resistance was 545 constant; when placed between the pole-pieces of an electromagnet and subjected to fields of various strengths up to nearly 30,000 units. At constant temperature the resistance increased with the field; the changes in the resistance of the spiral with the temperature were 18° C. indicated in the annexed table, from which it will be seen that in the strongest

At the temperature of liquid air ($-185$° C) the application of a field of 21,800 multiplied the resistance of the bismuth less than 150 times. Fig. 29 shows the variation of resistance in relation to temperature for the field $H=2450$° C. It will be seen that for $H=2450$° C and $H=5500$ the minimum resistance occurs at temperatures of about $-86°$ and $-7°$ respectively.

**Hall Effect.**—If an electric current is passed along a strip of thin metal, and the two points at opposite ends of an equipotential line are connected with a galvanometer, its needle will of course not be deflected. But the application of a magnetic field at right angles to the plane of the metal causes the equipotential lines to rotate through a small angle, and the points at
which the galvanometer is connected being no longer at the same potential, a current is indicated by the galvanometer.\(^1\)

The transverse electromotive force is equal to \(KCH/D\), where \(C\) is the current, \(H\) the strength of the field, \(D\) the thickness of the metal, and \(K\) a constant which has been termed the rotatory power or rotational coefficient. (See Hopkinson, Phil. Mag., 1886, 10, 439.) The following values of \(K\) for different metals are given by E. H. Hall, the positive sign indicating that the electromotive force is in the same direction as the mechanical force acting upon the conductor. A. von Ettinghausen and

W. Nernst (Wien. Ber., 1886, 94, 560) have found that the rotational coefficient of tellurium is more than fifty times greater than that of bismuth, its sign being positive. Several experimenters have endeavoured to find a Hall effect in liquids, but such results as have been hitherto obtained are by no means free from doubt. E. A. Marx (Ann. d. Phys., 1900, 2, 798) observed a well-defined Hall effect in incandescent gases.

Electro-Thermal Relations.—The Hall electromotive force is only one of several so-called "galvano-magnetic effects" which are observed when a magnetic field acts normally upon a thin plate of metal traversed by an electric current. It is remarkable that if a flow of heat be substituted for a current of electricity a closely allied group of "thermo-magnetic effects" is presented. The two classes of phenomena have been collated by M. G. Lloyd (Am. Journ. Sci., 1901, 12, 57), as follows:

Galvano-Magnetic Effects.
1. A transverse difference of electric potential (Hall effect).
2. A transverse difference of temperature (Ettinghausen effect).
3. Longitudinal change of electric conductivity.
4. Longitudinal difference of temperature.

Thermo-Magnetic Effects.
1. A transverse difference of electric potential (Nernst effect).
2. A transverse difference of temperature (Leduc effect).
3. Longitudinal change of thermal conductivity.
4. Longitudinal difference of electric potential.\(^2\)

In the annexed diagram ABCD represents the metallic plate through which the current of electricity or heat flows in the direction AB, then effects (1), (2), (i), and (ii) are exhibited at C and D, effects (4) and (iv) at A and B, and effects (3) and (iii) along AB. The transverse effects are exhibited in direction when either the magnetic field or the primary current (electric or thermal) is reversed, but the longitudinal effects are independent of the direction of the field. It has been shown by G. Moreau (C. R., 1900, 130, pp. 122, 412, 562) that if \(K\) is the coefficient of the Hall effect (1) and \(K'\) the analogous coefficient of the Nernst effect (ii) (which is constant for small values of \(H\)), then \(K' = \sigma H / \rho\), \(\sigma\) being the coefficient of the Thomson effect for the metal and \(\rho\) its specific resistance. He considers that Hall’s is the fundamental phenomenon, and that the Nernst effect is essentially identical with it, the primary electromotive force in the case of the latter being that of the Thomson effect in the unequally heated metal, while in the Hall experiment it is derived from an external source.

Attempts have been made to explain these various effects by the electron theory.\(^4\)

Thermo-electric Quality.—The earliest observations of the effect of magnetization upon thermo-electric power were those of W. Thomson (Lord Kelvin), who in 1836 announced that magnetization rendered iron and steel positive to the unmagnetized metals.\(^5\) It has been found by Chassagny,\(^6\) L. Houllevigue,\(^7\) and others that when the magnetizing force is increased, this effect passes a maximum, while J. A. Ewing\(^8\) has shown that it is diminished and may even be reversed by tensile stress. Nickel was believed by Thomson to behave oppositely to iron, becoming negative when magnetized; but though his conclusion was accepted for nearly fifty years, it has recently been shown to be an erroneous one, based, no doubt, upon the result of an experiment with an impure specimen. Nickel when magnetized is always positive to the unmagnetized metal. So also is cobalt, as was found by H. Tomlinson.\(^9\) The curves given by Houllevigue for the relation of thermo-electric force to magnetic field are of the same general form as those showing the relation of change of length to field. E. Rhoads\(^10\) obtained a cyclic curve for iron, which indicated thermo-electric hysteresis of the kind exhibited by Nagaoaka’s curves for magnetic strain. He also experimented with nickel and again found a resemblance to the strain curve. The subject was further investigated by S. Bidwell,\(^11\) who, adopting special precautions against sources of error by which former work was probably affected, measured the changes of thermo-electric force for iron, steel, nickel and cobalt produced by mechanical fields up to 1500 units. In the case of iron and nickel it was found that, when correction was made for mechanical stress due to magnetization, magnetic change of thermo-electric force was, within the limits of experimental error, proportional to magnetic change of length. Further, it was shown that the thermo-electric curves were modified both by tensile stress and by annealing in the same manner as were the change-of-length curves, the modification being sometimes of a complex nature. Thus a close connexion between the two sets of phenomena seems to be established. In the case of cobalt no such relation could be traced; it appeared that the thermo-electric potential of the unmagnetized with respect to the magnetized cobalt was proportional to the square of the magnetic induction or of the magnetization of nickel six.

\(^2\) Phil. Trans., 1886, p. 722. According to the nomenclature adopted by the best modern authorities, a metal \(A\) is said to be thermo-electrically positive to another metal \(B\) when the current-passing from \(A\) to \(B\) through the cold junction, and from \(B\) to \(A\) through the hot (see Thermo-Electricity).
\(^3\) C.R., 1893, 116, 997.
\(^4\) Journ. de Phys., 1896, 5, 53.
\(^5\) Phil. Trans., 1887, 177, 373.
\(^7\) Phys. Rev., 1902, 15, 321. The sign of the thermo-electric effect for nickel, as given by Rhoads, is incorrect.
different specimens were tested, all of which became, like iron, thermo-electrically positive to the unmagnetized metals.

As to what effect, if any, is produced upon the thermo-electric quality of bismuth by a magnetic field there is still some doubt. E. van Aubel believes that in pure bismuth the thermo-electric force is increased by the field; impurities may neutralize this effect, and in sufficient quantities reverse it.

**Elasticity.**—The results of experiments as to the effect of magnetization were for long discordant and inconclusive, sufficient care not having been taken to avoid sources of error, while the effects of hysteresis were altogether disregarded. The subject, which is of importance in connexion with theories of magnetostriiction, has been investigated by K. Honda and T. Teraoka; the researches on the remanence and the hysteresis of the experimental methods employed. The results are too numerous to discuss in detail; some of those to which special attention is directed are the following: In Swedish iron and tungsten-steel the change of elastic constants (Young's modulus and rigidity) is generally positive, but its amount is less than 0.5%; changes of Young's modulus and of rigidity are almost identical. In nickel the maximum change of the elastic constants is remarkably large, amounting to about 15% for Young's modulus and 7% for rigidity; with increasing fields the elastic constants first decrease and then increase. In nickel-steel, containing about 50 and 70% of nickel the maximum increase of the constants is as much as 7 or 8%. In a 20% nickel-steel, magnetization increases the constants by a small amount. Changes of elasticity are in all cases dependent, not only upon the field, but also upon the tension applied; and, owing to hysteresis, the results are not in general the same when the magnetization follows a known path. When it precedes the application of stress; the latter is held to be the right order.

**Chemical and Voltic Effects.**—If two iron plates, one of which is magnetized, are immersed in an electrolyte, a current will generally be indicated by a galvanometer connected with the plates.

As to whether the magnetized plate becomes positive or negative to the other, different experimenters are not in agreement. In this work, however, has been shown by Dragomir Hurguzescu (Rep. du Congrè Int. de Phys., Paris, 1906, p. 561) that the true effect of magnetization is liable to be disguised by secondary or parasitical phenomena, arising chiefly from polarization of the electrodes and from local variations in the concentration and magnetic condition of the electrolyte; these may be avoided by working with weak solutions, exposing only a small surface in a non-polarizing portion of the metal, and substituting a capillary electrometer for the galvanometer generally used. When such precautions are adopted it is found that the electromotive force of magnetization, is, for a given specimen, independent both in direction and in magnitude; it is independent of the nature of the corrosive solution, and is a function of the field-strength alone, the curves showing the relation of electromotive force to field-intensity bearing a rough resemblance to the familiar 1-n curves. The value of the E.M.F., when 11=2000 is that of 1000 volt for iron, 1/1000 volt for nickel and 1/10,000 for bismuth. When the two electrodes are ferro-magnetic, the direction of the current through the liquid is from the unmagnetized to the magnetized electrode, the latter being less attacked; with diamagnetic electrodes, the reverse is the case.

Hurguzescu shows that the electromotive forces are in accord with theory. Applying the principle of the conservation of internal energy, he demonstrates that for iron in a field of 1000 units and upwards the E.M.F. of magnetization is

\[ E = \frac{1}{11} 1 \frac{1}{11} \] approximately,

\( I \) being the electrochemical equivalent and \( \delta \) the density of the metal. Owing to the difficulty of determining the magnetization \( I \) and the susceptibility \( k \) with accuracy, it has not yet been possible to submit this formula to a quantitative test, but it is said to afford an indication of the results of experiments given by actual experiment. It has been discovered by E. L. Nichols and W. S. Franklin (Am. Journ. Sci., 1887, 34, 419; 1888, 35, 290) that the transition from the "passive" to the active state of iron immersed in strong nitric acid is facilitated by magnetization; this fact is connected with the action of local currents set up between unequally magnetized portions of the iron. Similar results have been obtained by T. Andrews (Proc. Roy. Soc., 1890, 48, 116).

---

**MAGNETISM**

**II. Feebly Susceptible Substances**

**Water.**—The following are recent determinations of the magnetic susceptibility of water:

<table>

Wills found that the susceptibility was constant in fields ranging from 4,200 to 15,000.

**Oxygen and Air.**—The best modern determinations of the value of \( k \) for gaseous oxygen agree very fairly well with that given by Faraday in 1853 (Exp. Res. Ill. 502). Assuming that for water \( k = 0.8 \times 10^{-4} \), his value of \( k \) for oxygen at 15°C. reduces to \( 0.15 \times 10^{-4} \). Important experiments on the susceptibility of oxygen at different pressures and temperatures were carried out by P. Curie (C. R., 1892, 112, 860; 1893, 116, 136). For air at 0°C., \( k = 0.174 \times 10^{-4} \). For air Curie calculated that the susceptibility per unit mass was \( k = 7.830/\theta \); or, taking the mass of 1 c.c. of air at 0°C. and 760 mm. pressure is \( 0.00141 \) grm., the mass at any absolute temperature \( \theta \) is by Charles's law \( 0.00141 \times 237\theta = 0.3840/\theta \) grm.; hence the susceptibility per unit of volume at 760 mm. will be

\[ k = 10^{-4} X \times 3840 \times 33700/\theta^2 = 10^{-4} \times 12970/\theta. \]

At 15°C. \( \theta = 273 + 25 = 298 \), and therefore \( k = 0.156 \times 10^{-4} \) as the same value found by Faraday. At 0°C., \( k = 0.174 \times 10^{-4} \). For air Curie calculated that the susceptibility per unit mass was \( 10^{-4} \delta = 7.830/\theta \); or, taking the mass of 1 c.c. of air at 0°C. and 760 mm. as \( 0.00141 \) grm., \( k = 10^{-4} X 2760/\theta \) for air at standard atmospheric pressure. It is pointed out that this formula may be used as a temperature correction in magnetic determinations carried out in air.

Fleming and Dewar determined the susceptibility of liquid oxygen (Proc. Roy. Soc., 1896, 65, 283; 1898, 63, 311). In their later experiments it was calculated from observations of the mutual induction of two conductor circuits in air and in the liquid; the results for oxygen at \( 18°C. \) were

\[ k = 228 \times 10^{-6}. \]

In the second series, to which greater importance is attached, measurements were made of the force exerted in a divergent field upon small balls of copper, silver and other substances, first when the balls were in air and afterwards when they were immersed in liquid oxygen. If \( V \) is the volume of a ball, \( H \) the strength of the field at its centre, and \( k' \) its apparent susceptibility, the force in the direction \( x \) is \( f = k' X VH \times dX \); and if \( k' \) and \( k'' \) are the apparent susceptibilities of the same ball in air and in liquid oxygen, \( k' - k'' \) is equal to the difference between the susceptibilities of the two media. The susceptibility of air being known—practically it was negligible in these experiments—that of liquid oxygen can at once be found. The mean of 36 experiments with 7 balls gave

\[ k = 324 \times 10^{-6}. \]

A small but decided tendency to a decrease of susceptibility in very strong fields was observed. It appears, therefore, that liquid oxygen is by far the most strongly paramagnetic liquid known, its susceptibility being more than four times greater than that of a saturated solution of ferric chloride.

On the other hand, its susceptibility is about fifty times less than that of Hadfield's 12% manganese steel, which is commonly spoken of as non-magnetizable.
**MAGNETISM**

**Bismuth.**—Bismuth is of special interest, as being the most strongly diamagnetic substance known, the mean value of the best determinations of its susceptibility being about \(-14 \times 10^{-6}\) (see G. Meslin, C. R., 1905, 140, 440). The magnetic properties of the metal at different temperatures and in fields up to 1350 units have been studied by P. Curie (loc. cit.), who found that its "specific susceptibility" \(K\) was independent of the strength of the field, but decreased with increase of temperature up to the melting-point, 273°C. His results appear to show the relation

\[
-K x 10^6 = 1381 - 0.00155t
\]

Assuming the density of Bi to be 9.8, and neglecting correction for heat dilatation, his value for the susceptibility at 20°C is equivalent to \(k = -13.23 \times 10^{-6}\). As the temperature was raised up to 273°C, \(k\) gradually fell to \(-9.38 \times 10^{-6}\), rising suddenly when fusion occurred to \(-0.37 \times 10^{-6}\), at which value it remained constant when the fluid metal was further heated. Fleming and Dewar give for the susceptibility the values \(-13.7 \times 10^{-6}\) at 15°C and \(-15.9 \times 10^{-6}\) at \(-182\), the latter being approximately equivalent to \(K x 10^6 = -1.62\). Putting \(F = -1.82\) in the equation given above for Curie's results, we get \(K x 10^6 = -1.66\), a value sufficiently near that obtained by Fleming and Dewar to suggest the probability that the diamagnetic susceptibility varies inversely as the temperature between \(-182\) and the melting-point.

**Other Diamagnetics.**—The following table gives Curie's determinations (Journ. de Phys., 1895, 4, 204) of the specific susceptibility \(K\) of other diamagnetic substances at different temperatures. It should be noted that \(K = k/density\).

For all diamagnetic substances, except antimony and bismuth, the value of \(K\) was found to be independent of the temperature.

**Paramagnetic Substances.**—Experiments by J. S. Townsend (Phil. Trans., 1866, 187, 533) show that the susceptibility of solutions of salts of iron is independent of the magnetising force, and depends only on the quantity of iron contained in unit volume of the liquid. If \(W\) is the weight of iron present per c.c. at about 10°C, then for ferric salts

\[
10^6k = 266W - 0.77
\]

and for ferrous salts

\[
10^6k = 206W - 0.77
\]

the quantity \(-0.77\) arising from the diamagnetism of the water of solution. Annexed are values of \(10^6k\) for the different salts examined, \(w\) being the weight of the salt per c.c. of the solution.

Suscceptibility was found to diminish greatly with rise of temperature. According to G. Jäger and S. Meyer (Wien. Akad. Sitz., 1897, 106, II.a, p. 623, and 1898, 107, II.a, p. 5) the atomic susceptibilities \(k\) of the metals nickel, chromium, iron, cobalt and manganese in solutions of their salts are as follows:

Fe(1) is iron contained in FeCl₃ and Fe(2) iron contained in Fe₂(NO₃)₉.

Curie has shown, for many paramagnetic bodies, that the specific susceptibility \(K\) is inversely proportional to the absolute temperature \(T\). Du Bois believes this to be an important general law, applicable to the case of every paramagnetic substance, and suggests that the product \(K^{-1}\) should be known as "Curie's constant" for the substance.

**Elementary Bodies and Atomic Susceptibility.**—Among a large number of substances the susceptibilities of which have been determined by J. Koenigsberger (Wied. Ann., 1898, 66, 609) are the following elements:

In a table accompanying Koenigsberger's paper the elements are arranged upon the periodic system and the atomic susceptibility (product of specific susceptibility into atomic weight) is given for each. It appears that the elements at the middle of each row are the most strongly paramagnetic; towards the ends of a row the susceptibility decreases, and ultimately becomes negative. Thus a relation between susceptibility and atomic weight is clearly indicated. Tables similarly arranged, but much more complete, have been published by S. Meyer (Wied. Ann., 1899, 68, 325 and 1899, 69, 236), whose researches have filled up many previously existing gaps. The values assigned to the atomic susceptibilities of most of the known elements are appended. According to the notation adopted by Meyer the atomic susceptibility \(k = kx\) atomic weight/\(\times 1000\).

Meyer thinks that the susceptibilities of the metals praseodymium, neodymium, ytterbium, samarium, gadolinium, and erbium, when obtained in a pure form, will be found to equal or even exceed those of the well-known ferromagnetic metals. Many of their compounds are very strongly magnetic; for example, in ErO₃ being four times as strong as iron in the familiar magnetite or lodestone.

Fe₂O₃. The susceptibilities of some hundreds of inorganic compounds have also been determined by the same investigator (loc. cit.). Among others, those whose magnetic moment is molecular are those of O. Liebknecht and A. P. Wills (Journ. de Phys., 1900, 1, 178), H. du Bois and O. Liebknecht (ibid. p. 189), and Meyer (ibid. p. 668). An excellent summary regarding the magnetic properties of matter, with many tables and references, has been compiled by du Bois (Report to the Congrès Int. de Phys., Paris, 1906, ii. 460).
12. Molecular Theory of Magnetism

According to W. E. Weber's theory, the molecules of a ferromagnetic metal are small permanent magnets, the axes of which under ordinary conditions are turned indifferently in every direction, so that no magnetic polarity results corresponding to the metal as a whole; a magnetic force acting upon the metal tends to turn the axes of the little magnets in one direction, and thus the entire piece acquires the properties of a magnet. If, however, the molecules could turn with perfect freedom, it is clear that the smallest magnetizing force would be sufficient to develop the highest possible degree of magnetization, which is of course not the case. Weber therefore supposed each molecule to be acted on by a force tending to preserve it in its original direction, the position actually assumed by the axis being in the direction of the resultant of this hypothetical force and the applied magnetizing force. Maxwell (Electricity and Magnetism, § 444), recognizing that the theory in this form gave no account of residual magnetization, made the further assumption that if the deflection of the axis of the molecule exceeded a certain angle, the axis would not return to its original position when the deflecting force was removed, but would retain a permanent set. Although the amended theory as worked out by Maxwell is in accordance with the leading phenomena of magnetization, it fails to account for many others, and is in some cases at variance with observed facts.

J. A. Ewing (Proc. Roy. Soc., 1890, 48, 342) has demonstrated that it is quite unnecessary to assume either the directive force of Weber, the permanent set of Maxwell, or any kind of frictional resistance, the forces by which the molecular magnets are constrained being simply those due to their own mutual attractions and repulsions. The effect of these is beautifully illustrated by a model consisting of a number of little compass needles pivoted on sharp points and grouped near to one another upon a board, which is placed inside a large magnetizing coil. When no current is passing through the coil and the magnetic field is of zero strength, the needles arrange themselves in positions of stable equilibrium under their mutual forces, pointing in many different directions, so that there is no resultant magnetic moment. This represents the condition of the molecules in unmagnetized iron. If now a gradually increasing magnetizing force is applied, the needles at first undergo a stable deflection, giving to the group a small resultant moment which increases uniformly with the force; and if the current is interrupted while the force is still weak, the needles merely return to their initial positions. This illustrates the first stage in the process of magnetization, when the moment is proportional to the field and there is no hysteresis or residual magnetism (see ante). A somewhat stronger field will deflect many of the needles beyond the limits of stability, causing them to turn round and form new stable combinations, in which the direction assumed by most of them approximates to that of the field. The rearrangement is completed within a comparatively small range of magnetizing force, a rapid increase of the resultant moment being thus brought about. When the field is removed, most of the newly formed combinations are but slightly disturbed, and the group may consequently retain a considerable resultant moment. This corresponds to the second stage of magnetization, in which the susceptibility is large and permanent magnetization is set up. A still stronger magnetizing force has little effect except in causing the direction of the needles to approach still more nearly to that of the field; if the force were infinite, every member of the group would have exactly the same direction and the greatest possible resultant moment would be reached; this illustrates "magnetic saturation" — the condition approached in the third stage of magnetization. When the strong magnetizing field is gradually diminished to zero and then reversed, the needles pass from one stable position of rest to another through a condition of instability; and if the field is once more reversed, so that the cycle is completed, the needles again pass through a condition of instability before a position of stable equilibrium is regained. Now the unstable movements of the needles are of a mechanically irreversible character; the energy expended in dissociating the members of a combination and placing them in unstable positions assumes the kinetic form when the needles turn over, and is ultimately frettered down sodistributed as to cause the needle to be carried by a train of points around the circle that would have corresponded to what has been termed hysteresis-loss. Supposing Ewing's hypothesis to be correct, it is clear that if the magnetization of a piece of iron were reversed by a strong rotating field instead of by a field alternating through zero, the loss of energy by hysteresis should be little or nothing, for the molecules would rotate with the field and no unstable movements would be possible. Some experiments by F. G. Baily (Phil. Trans., 1896, 187, 715) show that this is actually the case. With small magnetizing forces the hysteresis was indeed somewhat larger than that obtained in an alternating field, probably on account of the molecular changes being forced to take place in one direction only; but at an induction of about 16,000 units in soft iron and 15,000 in hard steel the hysteresis reached a maximum and afterwards rapidly diminished. In one case the hysteresis loss per cubic centimetre per cycle was 16,100 ergs for B=15,000, and only 1200 ergs for B=20,000, the highest induction obtained in the experiment possibly it would have vanished before B had reached 21,000. These experiments prove that actual friction must be almost entirely absent, and, as Baily remarks, the agreement of the results with the previously suggested deduction affords a strong verification of Ewing's form of the molecular theory. Ewing has himself also shown how satisfactorily this theory accords with many other obscure and complicated phenomena, such as those presented by coercive force, differences of magnetic quality, and the effects of vibration, temperature and stress; while as regards simplicity and freedom from arbitrary assumptions it leaves little to be desired.

The fact being established that magnetism is essentially a molecular phenomenon, the next step is to inquire what is the constitution of a magnetic molecule, and why it is that some molecules are ferromagnetic, others paramagnetic, and others again diamagnetic. The best known of the explanations that have been proposed depend upon the magnetic action of an electric current. It can be shown that if a current i circulates in a small plane circuit of area S, the magnetic action of the circuit for distant points is equivalent to that of a short magnet whose axis is perpendicular to the plane of the circuit and whose moment is iS, the direction of the magnetization being related to that of the circulating current as the thrust of a right-handed screw to its rotation. Ferromagnetism was explained by Ampère on the hypothesis that the magnetization of the molecule is due to an electric current constantly circulating within it. The theory now most in favour is merely a development of Ampère's hypothesis, and applies not only to ferromagnetics, but to paramagnetics as well. To account for diamagnetism, Weber supposed that there exist within the molecules of diamagnetic substances certain channels around which an electric current can circulate without any resistance. The creation of an additional moment H will, in accordance with Lenz's law, induce in the molecule an equal and opposite circular current, so that the magnetization of the equivalent magnet is opposite to the direction of the field. The strength of the induced current is \(-H\cos \theta /L\), where \(\theta\) is the inclination of the axis of the circuit to the direction of the field, and L the coefficient of self-induction; the resolved part of the magnetic moment in the direction of the field is equal to \(-H\cos \theta /L\), and if there are n molecules in a unit of volume, their axes being distributed indifferently in all directions, the magnetization of the substance will be \(-H\cos \theta /L\), and its susceptibility \(-\mu^2 /L\) (Maxwell, Electricity and Magnetism, § 838). The susceptibility is therefore constant and independent of the field, while its negative sign indicates that the substance is diamagnetic. There being no resistance, the induced current will continue to circulate.

1 This deduction from Ewing's theory appears to have been first suggested by J. Swinburne. See Industries, 1890, 289.

2 R. Beattie (Phil. Mag., 1901, 1, 642) has found similar effects in nickel and cobalt.
MAGNETISM

round the molecule until the field is withdrawn, when it will be
topped by the action of an electro-motive force tending to
induce an exactly equal current in the opposite direction. The
principle of Weber's theory, with the modification necessitated
by lately acquired knowledge, is the basis of the best modern
explanation of diamagnetic phenomena.

There are strong reasons for believing that magnetism is a
phenomenon involving rotation, and as early as 1876 Rowland,
carrying out an experiment which had been proposed by Maxwell,
showed that a revolving electric charge produced the same
magnetic effects as a current. Since that date it has more than
once been suggested that the molecular currents producing
magnetism might be due to the revolution of one or more of the
charged atoms or "ions" constituting the molecule. None of the
detailed hypotheses which were based on this idea stood the
test of criticism, but towards the end of the 19th century the
researches of J. J. Thomson and others once more brought the
conception of moving electric charges into prominence. Thomson
has demonstrated the existence under many different conditions
of particles more minute than anything previously known to
science. The mass of each is about \( \frac{1}{18} \)th part of that of a
hydrogen atom, and with each is indissolubly associated a charge
of negative electricity equal to about \( 3.2 \times 10^{-19} \) C.G.S. electro-
static unit. These particles, which were termed by their dis-
coverers corpuscles, are more commonly spoken of as electrons, a
particle thus being identified with the charge which it carries.
An electrically neutral atom is believed to be constituted in part,
or perhaps entirely, of a definite number of electrons in rapid
motion within a "sphere of uniform positive electrification" not
yet explained. One or more of the electrons may be detached
from the system by a finite force, the number so detachable
depending on the valency of the atom; if the atom loses an
electron, it becomes positively electrified; if it receives additional
electrons, it is negatively electrified. The process of electric con-
duction in metals consists in the movement of detached electrons,
and many other phenomena, both electrical and thermal, can be
more or less completely explained by their agency. It has been
supposed that certain electrons revolve like satellites in orbits
around the atoms with which they are associated, a view which
receives strong support from the phenomena of the Zeeman effect,
and on this assumption a theory has been worked out by P. Langevin, a which accounts for many of the observed facts of
magnetism. As a consequence of the structure of the molecule,
which is an aggregation of atoms, the planes of the orbits around
the latter may be oriented in various positions, and the direction
of revolution may be right-handed or left-handed with respect
to the direction of any applied magnetic field. For those orbits
whose projection upon a plane perpendicular to the field is right-
handed, the period of revolution will be accelerated by the field
(since the electron current is negative), and the magnetic moment
consequently increased; for those which are left-handed, the
period will be retarded and the moment diminished. The
effect of the field upon the speed of the revolving electrons, and
therefore upon the moment, is determined by the equivalent magnets,
which is necessarily a very small one. If \( S \) is the area of the orbit
described in time \( \tau \) by an electron of charge \( e \), the moment of the
equivalent magnet is \( M = eS\tau \); and the change in the value
of \( M \) due to an external field \( H \) is shown to be
\[
\Delta M = -H eS / 4\pi m
\]

According to the best determinations the value of \( e/m \) does not
exceed \( 1.8 \times 10^{-18} \), and \( \tau \) is of the order of \( 10^{-14} \) second,
the period of luminous vibrations; hence \( \Delta M / M \) must always be less
than \( 10^{-11} \), and therefore the strongest fields yet reached
experimentally, which fall considerably short of \( 10^9 \), could not
change the magnetic moment \( M \) by as much as a ten-thousandth
part. If the structure of the molecule is so perfectly symmetrical
that, in the absence of any external field, the resultant magnetic
moment of the circulating electrons is zero, then the application
of a field, by accelerating the right-handed (negative) revolutions,
and retarding those which are left-handed, will induce in the
substance a resultant magnetization opposite in direction to the
field itself; a body composed of such symmetrical molecules is
therefore diamagnetic. If however the structure of the mole-
cule is such that the electrons revolving around its atoms
do not exactly cancel one another's effects, the molecule
constitutes a little magnet, which under the influence of an
external field will tend to set itself with its axis parallel to the
field. Ordinarily a substance composed of asymmetrical mole-
cules is paramagnetic, but if the elementary magnets are not
conditioned by their strength and concentration that mutual
action between them is possible, then the substance is ferro-
magnetic. In all cases however it is the diamagnetic condition
that is initially set up—even iron is diamagnetic—though the
diamagnetism may be completely masked by the superposed
paramagnetic or ferromagnetic condition. Diamagnetism, in
short, is an atomic phenomenon; paramagnetism and ferro-
magnetism are molecular phenomena. Hence may be deduced
an explanation of the fact that, while the susceptibility of all
known diamagnetics (except bismuth and antimony) is inde-
pendent of the temperature, that of paramagnetics varies
inversely as the absolute temperature, in accordance with the
law of Curie.

13. HISTORICAL AND CHRONOLOGICAL NOTES

The most conspicuous property of the lodestone, its attraction
for iron, appears to have been familiar to the Greeks at least as
early as 800 B.C., and is mentioned by Homer, Plato, Aristotle,
Theophrastus and others. A passage in De rerum natura (vi.
910–915) by the Roman poet, Lucretius (96–55 B.C.), in which
it is stated that the stone can support a chain of little rings, each
adhering to the one above it, indicates that in his time the phenome-
on of magnetization by induction had also been observed.
The property of orientation, in virtue of which a freely suspended
magnet points approximately to the geographical north and
south, is not referred to by any European writer before the 12th
century, though it is said to have been known to the Chinese at
a much earlier period. The application of this property to the
construction of the mariner's compass is obvious, and it is in
connexion with navigation that the first references to it occur
(see Compass). The needles of the primitive compasses, being
made of iron, would require frequent re-magnetization, and a
"stone" for the purpose of "touching the needle" was therefore
generally included in the navigator's outfit. With the constant
practice of this operation it is hardly possible that the repulsion
acting between like poles should have entirely escaped recogni-
tion; but though it appears to have been noticed that the lode-
stone sometimes repelled iron instead of attracting it, no clear
statement of the fundamental law that unlike poles attract while
like poles repel was recorded before the publication in 1581 of the
New Attractio by Robert Norman, a pioneer in accurate magnetic
work. The same book contains an account of Norman's dis-
coveries and correct measurement of the dip (1576). The
downward tendency of the north pole of a magnet pivoted in the usual
way had been observed by G. Hartmann of Nürnberg in 1544,
but his observation was not published till much later.

The foundations of the modern science of magnetism were laid
by William Gilbert (q.v.). His De magnete magnetico
corporibus et de magneto magnetarum tellure physiologia nova (1600),
contains many references to the expositions of earlier writers
from Plato down to those of the author's own age. These show that
the very few facts known with certainty were freely supplemented
by a number of ill-founded conjectures, and sometimes even
by "figments and falsehoods, which in the earliest times, no
less than nowadays, used to be put forth by raw smatterers
and copyists to be swallowed of men." Thus it was taught
that "if a lodestone be anointed with garlic, or if a diamond be
near, it does not attract iron," and that "if pickled in the salt
of a sucking fish, there is power to pick up gold which has
fallen into the deepest wells." There were said to be "various
kinds of magnets, some of which attract gold, others silver, brass,
lead; even some which attract flesh, water, fishes;" and stories
were told about "mountains in the north of such great powers of
attraction that ships are built with wooden pegs, lest the iron
nails should be drawn from the timber." Certain occult powers
were also attributed to the stone. It was "of use to thieves by its
fume and sheen, being a stone born, as it were, to aid thee," and
even physicians and locks; it was effective as a love-potion, and
possessed "the power to reconcile husbands to their wives, and
to recall brides to their husbands." And much more of the same
kind, which, as Gilbert says, had come down "even to [his] own
day through the writings of a host of men, who, to fill out their
volumes to a proper bulk, write and copy out pages upon pages
on this, and the other subject, of which they know almost
nothing for certain of their own experience." Gilbert himself
absolutely disregarded authority, and accepted nothing at
second-hand. His title to be honoured as the "Father of
magnetick Philosophy" is based even more largely upon the
scientific method which he was the first to inculcate and practise
than upon the importance of his actual discoveries. Careful
experiment and observation, not the innate and unreasoning
pride, the only foundations of true science. Nothing has been
set down in his book "which hath not been explored and
many times performed and repeated" by himself. "It is very
easy for men of acute intellect, apart from experiment and
practice, to slip and err." The greatest of Gilbert's discoveries
was that the globe of the earth was magnetic and a magnet;
the evidence by which he supported this view was derived chiefly
from ingenious experiments made with a spherical lodestone or
terrælla, as he termed it, and from his original observation that an
iron bar could be magnetized by the earth's force. He also carried
out some new experiments on the effects of heat, and of screening
by magnetic substances, and investigated the influence of
shape upon the magnetization of iron. But the bulk of his
work consisted in imparting scientific definiteness to what was
already vaguely known, and in demolishing the errors of his
predecessors.

No material advance upon the knowledge recorded in Gilbert's
book was made until the establishment by Coulomb in 1785 of
the law of magnetic action. The difficulties attending the
experimental investigation of the forces acting between magnetic
poles have already been referred to, and indeed a rigorously exact
determination of the mutual action could only be made under
conditions which are in practice unattainable. Coulomb, however,
by using long and thin steel rods, symmetrically magnetized,
and so arranged that disturbing influences became negligibly
small, was enabled to deduce from his experiments with reason-
able certainty the law that the force of attraction or repulsion
between two magnetic poles is proportional to the product of the
influence of each pole and the distance between them. Several previous attempts had been made to
discover the law of force, with various results, some of which
correctly indicated the inverse square; in particular the German
astronomer, J. Tobias Mayer (Gött. Ameisger, 1750), and the
Aalstian mathematician, J. Heinrich Lambert (Hist. de l'Acad.
Roy. Berlin, 1766, p. 22), may fairly be credited with having
anticipated the law which was afterwards more satisfactorily
established by Coulomb. The accuracy of this law was in 1832
confirmed by Gauss, who employed an indirect but more perfect
method than that of Coulomb, and also, as Maxwell remarks,
by all observers in magnetic observatories, who are every day
making measurements of magnetic quantities, and who obtain
results which would be inconsistent with each other if the law
of force had been erroneously assumed.

Coulomb's researches provided data for the development of a
mathematical theory of magnetism, which was indeed initiated
by himself, but was first treated in a complete form by Poisson
in a series of memoirs published in 1821 and later. Poisson
assumed the existence of two dissimilar magnetic fluids, any
element of which acted upon any other distant element in accord-
ance with Coulomb's law of the inverse square, like repelling and
unlike attracting one another. A magnetizable substance was
supposed to consist of an indefinite number of spherical particles,
each containing equivalent quantities of the two fluids, which
when free in the air, were at rest relatively to one another, but
when the fluids inside a particle were mixed together, the particle was neutral; when they were more or
less completely separated, the particle became magnetized to
an intensity depending upon the magnetic force applied; the
whole body therefore consisted of a number of little spheres
having north and south poles, each of which exerted an elementary
action at a distance. Upon this hypothesis Poisson investigated
the forces due to bodies magnetized in any manner, and also
originated the mathematical theory of magnetic induction. The
general confirmation by experiment of Poisson's theoretical
results created a tendency to regard his hypothetical magnetic
fluids as having a real existence; but it was pointed out by
W. Thomson (afterwards Lord Kelvin) in 1849 that while no
physical evidence could be adduced in support of the hypothesis,
certain discoveries, especially in electromagnetism, rendered
it extremely improbable (Reprint, p. 344). Regarding it as impor-
tant that all reasoning with reference to magnetism should be
conducted without any uncertain assumptions, he worked out a
mathematical theory upon the sole foundation of a few well-
known facts and principles. The results were substantially
the same as those given by Poisson's theory, so far as the latter
went, the principal additions including a fuller investigation
of magnetic distribution, and the theory of magnetic induction
in aeolotropic or crystalline substances. The mathematical
theory which was constructed by Poisson, and extended and
freed from doubtful hypotheses by Kelvin, has been elaborated
by other investigators, notably F. E. Neumann, G. R. Kirchhoff,
and Helmholtz. The valuable work of Gauss on magnetic theory
and measurements, especially in relation to terrestrial mag-
tism, was published in his Intensitas vis magneticae terrestris,
1833, and in memoirs communicated to the Resultate aus den Beobacht-
ungen des magnetischen Vereins, 1838 and 1839, which, with
others, are contained in vol. 5 of the collected Werke. Weber's
molecular theory, which has already been referred to, appeared in
1852. An event of the first importance was the discovery made in
1810 by H. C. Oersted that a magnet placed near a wire carrying
an electric current tended to set itself at right angles to the wire,
a phenomenon which indicated that the current was surrounded
by a magnetic field. This discovery constituted the foundation
of electromagnetism, and its publication in 1820 was immediately
followed by the work of Faraday. The remarkable experimental
and theoretical investigation of the mutual action of electric currents, and of the equivalence of a closed circuit to a polar magnet, the latter suggesting his celebrated hypothesis that molecular currents were
the cause of magnetism. In the same year D. F. Arago s uc-
ces ed in magnetizing a piece of iron by the electric current, and
in 1825 W. Sturgeon 8 publicly exhibited an apparatus "acting

MAGNETISM, TERRESTRIAL

353

on the principle of powerful magnetism and feeble galvanism" which is believed to have constituted the first actual electromagnet. Michael Faraday's researches were begun in 1831 and continued for more than twenty years. Among the most splendid of his achievements was the discovery of the phenomena and laws of magne-to-electric induction, the subject of two papers communicated to the Royal Society in 1831 and 1832. Another was the magnetic rotation of the plane of polarization of light, which was effected in 1845, and for the first time established a relation between light and magnetism. This was followed at the close of the same year by the discovery of the magnetic condition of all matter, a discovery which initiated a prolonged and fruitful study of paramagnetic and diamagnetic phenomena, including magnetocrystalline action and "magnetic conducting power," now known as permeability. Throughout his researches Faraday paid special regard to the medium as the true seat of magnetic action, and well-known results of his investigation guided him to the conception of "lines of force," or of induction, which he considered to be "closed curves passing in one part of the course through the magnet to which they belong, and in the other part through space," always tending to shorten themselves, and repelling one another when they were side by side (Exp. Res. §§ 3266-8, 3271). In 1873 James Clerk Maxwell published his classical Treatise on Electricity and Magnetism, in which Faraday's ideas were translated into a mathematical form. Maxwell explained electric and magnetic forces, not by the action at a distance assumed by the earlier mathematicians, but by stresses in a medium filling all space, and possessing qualities like those attributed to the old luminiferous ether. In particular, he found that the calculated velocity with which it transmitted electromagnetic disturbances was equal to the observed velocity of light; hence he was led to believe, not only that his medium and the ether were one and the same, but, further, that light itself was an electric and magnetic phenomenon. The experimental verification of Maxwell's views by H. R. Hertz in 1887 (Wied. Ann., 1888, 34, 155, 551, 600; and later works) they have commanded universal assent, and his methods are adopted in all modern work on electricity and magnetism.

The practice of measuring magnetic induction and permeability with scientific accuracy was introduced in 1873 by H. A. Rowland, whose careful experiments led to general recognition of the fact previously ignored by nearly all investigators, that magnetic susceptibility and permeability are by no means constants (at least in the case of the ferromagnetic metals) but functions of the magnetizing force. New light was thrown upon many important details of magnetic science by J. A. Ewing's Experimental Researches of 1855; throughout the whole of his work special attention was directed to that curious lagging action to which the author applied the now familiar term "hysteresis." His Historical and Experimental Researches in Electricity, published in 1890, presented for the first time a simple and sufficient explanation of hysteresis and many other complexities of magnetic quality. The amazing discoveries made by J. J. Thomson in 1897 and 1898 resulted in the establishment of the electron theory, which has already effectually developed an almost revolutionary character in more than one branch of science. The application of the theory by P. Langevin to the case of molecular magnetism has been noticed above, and there can be little doubt that in the near future it will contribute to the solution of other problems which are still obscure.

Historical.

The terrestrial magnetism has a long history. Its early growth was slow, and considerable uncertainty prevails as to its earliest developments. The properties of the magnet (see MAGNETISM) were to some small extent known to the Greeks and Romans before the Christian era, and compasses (see COMPASS) of an elementary character seem to have been employed in Europe at least as early as the 12th century. In China and Japan compasses of a kind seem to have existed at a much earlier date, and it is even claimed that the Chinese were aware of the declination of the compass needle from the true north before the end of the 11th century. Early scientific knowledge was usually, however, a mixture of facts, very imperfectly ascertained, with philosophic imaginings. When an early writer makes a statement which to a modern reader suggests a knowledge of the declination of the compass, he may have had no such definite idea in his mind. So far as Western civilization is concerned, Columbus is usually credited with the discovery—in 1492 during his first voyage to America—that the pointing of the compass needle to the true north represents an exceptional state of matters, and that a declination in general exists, varying from place to place. The credit of these discoveries is not, however, universally conceded to Columbus. G. Hellmann 6 considers it almost certain that the departure of the needle from the true north was known in Europe before the time of Columbus. There is indirect evidence that the declination of the compass was not known in Europe in the early part of the 15th century, through the peculiarities shown by early maps believed to have been drawn solely by regard to the compass. Whether Columbus was the first to observe the declination or not, his date is at least approximately that of its discovery.

The next fundamental discovery is usually ascribed to Robert Norman, an English instrument maker, in The Newe Attractive (1581) Norman describes his discovery made some years before of the inclination or dip. The discovery was made more or less by accident, through Norman's noticing that compass needles which were truly balanced so as to be horizontal when unmagnetized, ceased to be so after being stroked with a magnet. Norman devised a form of dip-circle, and found a value for the inclination in London which was at least not very wide of the mark.

Another fundamental discovery, that of the secular change of the declination, was made in England by Henry Gellibrand, professor of mathematics at Gresham College, who described it in his Discourse Mathematical on the Variation of the Magnetic Needle together with its Admirable Diminution lately discovered (1635). The history of this discovery affords a curious example of long knowledge. William Borough, in his Discourse on the Variation of the Compass Magnet (London, 1651), gave for the declination at Limehouse in October 1580 the value 11° 1' E. approximately. Observations were repeated at Limehouse, Gellibrand tells us, in 1622 by his colleague Edmund Gunter, professor of astronomy at Gresham College, who found the much smaller value 6° 13'. The difference seems to have been ascribed at first to error on Borough's part, and no suspicion of the truth seems to have been felt until 1633, when some rough observations gave a value still lower than that found by Gunter.

* For explanation of these numbers, see end of article.
MAGNETISM, TERRESTRIAL

It was not until midsummer 1634 that Gellibrand felt sure of his facts, and yet the change of declination since 1580 exceeded 7°. The delay probably arose from the strength of the preconceived idea, apparently universally held, that the declination was absolutely fixed. This idea, it would appear, derived some of its strength from the positive assertion made on the point by Gilbert of Colchester in his De magnete (1600).

A third fundamental discovery, that of the diurnal change in the declination, is usually credited to George Graham (1675–1751), a London instrument maker. Previous observers, e.g., Gellibrand, had obtained slightly different values for the declination at different hours of the day, but it was natural to assign them to instrumental uncertainties. In those days the usual declination instrument was the compass with pivoted needles, and Graham himself at first assigned the differences he observed to friction. The observations on which he based his conclusions were made in 1722; an account of them was communicated to the Royal Society, and published in the Philosophical Transactions for 1724.

The movements of the compass needle throughout the average day represent partly a regular diurnal variation, and partly irregular changes in the declination. The distinction, however, was not at first very clearly realized. Between 1756 and 1759 J. Canton observed the declination-changes on some 600 days, and was thus able to deduce their general character. He found that the most prominent part of the regular diurnal change in England consisted of a westerly movement of the north-pointing pole from 8 or 9 a.m. to 1 or 2 p.m., followed by a more leisurely return movement to the east. He also found that the amplitude of the movement was considerably larger in summer than in winter. Canton further observed that in a few days the movements were conspicuously irregular, and that aurora was then visible. This association of magnetic disturbance and aurora had, however, been observed somewhat before this time, a description of one conspicuous instance being contributed to the Royal Society in 1759 by Pehr Vilhelm Wargentin (1717–1783), a Swede.

Another landmark in the history of terrestrial magnetism was the discovery towards the end of the 18th century that the intensity of the resultant magnetic force varies at different parts of the earth. The first observations clearly showing this seem to be those of a Frenchman, Paul de Lamanon, who observed in 1785–1787 at Teneriffe and Macao, but his results were not published at the time. The first published observations seem to be those made by the great traveller Humboldt in tropical America between 1798 and 1803. The delay in this discovery may again be attributed to instrumental imperfections. The method first developed for comparing the force at different places consisted in taking the time of oscillation of the dipping needle, and even with modern circles this is hardly a method of high precision. Another discovery worth chronicling was made by Arago in 1827. From observations made at Paris he found that the inclination of the dipping needle and the intensity of the horizontal component of the magnetic force both possessed a diurnal variation.

§ 2. Whilst Italy, England and France claim most of the early observational discoveries, Germany deserves a large share of credit for the great improvement in instruments and methods during the first half of the 19th century. Measurements of the intensity of the magnetic force were somewhat crude until Gauss showed how absolute results could be obtained, and not merely relative data based on observations with some particular needle. Gauss also devised the bifilar magnetometer, which is still largely represented in modern schemes of the horizontal force; but much of the practical success attending the application of his ideas to instruments seems due to Johann von Lamont (1825–1879), a Jesuit of Scottish origin resident in Germany.

The institution of special observatories for magnetic work is largely due to Humboldt and Gauss. The latter's observatory at Göttingen, where regular observations began in 1834, was the centre of the Magnetic Union founded by Gauss and Weber for the carrying out of simultaneous magnetic observations and it was long customary to employ Göttingen time in schemes of international co-operation.

In the next decade, mainly through the influence of Sir Edward Sabine (1788–1883), afterwards president of the Royal Society, several magnetic observatories were established in the British colonies, at St. Helena, Cape of Good Hope, Hobarton (now Hobart) and Toronto. These, with the exception of Toronto, continued in full action for only a few years; but their records—from their widely distributed positions—threw much fresh light on the differences between magnetic phenomena in different regions of the globe. The introduction of regular magnetic observatories led ere long to the discovery that there are notable differences between the amplitudes of the regular daily changes and the frequency of magnetic disturbances in different years. The discovery that magnetic phenomena have a period closely similar to, if not absolutely identical with, the eleven years' sunspot period was made independently and nearly simultaneously about the middle of the 19th century by Lamont, Sabine and R. Wolf.

The last half of the 19th century showed a large increase in the number of observatories taking magnetic observations. After 1890 there was an increased interest in magnetic work. One of the contributory causes was the magnetic survey of the British Isles made by Sir A. Rücker and Sir T. E. Thorpe, which served as a stimulus to similar work elsewhere; another was the institution by L. A. Bauer of a magazine, Terrestrial Magnetism, specially devoted to the subject. This increased activity added largely to the stock of information, sometimes in forms of marked practical utility; it was also manifested in the publication of a number of papers of a speculative character. For historical details the writer is largely indebted to the works of E. Walker and L. A. Bauer.

§ 3. All the more important magnetic observatories are provided with instruments of two kinds. Those of the first kind give the absolute value of the magnetic elements at the time of observation. The universal magnetometer (U.M.) and the dip circle give the inclination of the dipping needle. Instruments of the second kind, termed magnetographs (g.m.), are differential and self-recording, and show the changes constantly taking place in the magnetic elements. The ordinary form of magnetograph records photographically. Light reflected from a fixed mirror gives a base line corresponding to a certain value of the element; the light is cut off every hour or second hour so that the base line also serves to make the time. Light reflected from a mirror carried by a magnet gives a curved line answering to the changes in the magnetic elements, the length of the curve or perpendicular drawn from any point of the curved line on to the base line is proportional to the extent of departure of the magnet from a standard position. If then we know the absolute value of the element which corresponds to the base line, and the equivalent of 1 cm. of ordinate, we can deduce the absolute value of the element answering to any given instant of time. The deviation of the true value of 1 cm. of ordinate is usually dependent almost entirely on the distance of the mirror carried by the magnet from the photographic paper, and so remains invariable or very nearly so. In the case of the horizontal force and vertical force being the two force components usually recorded—the value of 1 cm. of ordinate is to the strength of the magnet. It has thus to be determined from time to time by observing the deflection shown on the photographic paper when a known magnet of known moment, at a measured distance, deflects the magnetograph mirror. The value of the ordinate is then altered to give the sensitiveness, for instance, by changing the effective distance in the bifilar suspension of the horizontal force magnet, and by altering the height of a small weight carried by the vertical force magnet. It is customary to aim at keeping the sensitiveness as constant as possible. A very common standard is to have 1 cm. of ordinate corresponding to 10° of arc in the declination and to 50y (1 y = 1′′ = 34–6 W). The curves are measured at the places which correspond to the times of the four observations, and the mean length of the four ordinates is, let us say, 2–5 cm. If 1 cm. answers to 10°, then 2–5 cm. represents 34–6 and the value which the declination would have if the curve came down to the base line—is for the month in question 16° 34–6 less 25–2 or
16° 4'. If now we wish to know the declination at any instant in this particular month all we have to do is to measure the corresponding ordinate and add its value, at the rate of 10' per cm., to the base value 16° 4'. Just found. Matters are a little more complicated in the case of the vertical force and two auxiliary instruments are required. These instruments usually possess a sensitive temperature coefficient, i.e., the position of the magnet is dependent to some extent on the temperature it happens to possess, and allowance has thus to be made for this in the observed results. It is obtained from a knowledge of the vertical force an "observed" value is derived by combining the observed value of the inclination with the simultaneous value of the horizontal force derived from the horizontal force magnetograph after the base value of the latter has been determined. It is the advantage of the results of the auxiliary instruments that their variation is small, and they are of interest. Their main importance is that they provide the means of fixing the value of the base line in the curves. Unless they are made carefully and sufficiently often the information derived from the curves suffers in accuracy, especially that relating to the secular change. It is from them that information is derived as to the regular diurnal variation and irregular changes. In some observatories it is customary to publish a complete set of daily deflections for each month. This is the regular diurnal variation, and by comparing it with the position of the sun and moon at each observation it is shown that one "accident" can be trusted to practically neutralize another, but this is much less true when the period is as short as a day. To meet this difficulty it is customary at some observatories to allow for an undisturbed day, and to reduce the disturbance to an average of many disturbed days. This is known as "diurnal inequalities," and it is the practice at some observatories to derive diurnal inequalities from a comparatively small number of undisturbed or quiet days. Beginning with 1890, five days a month were selected at Greenwich by the astronomers. The values of the magnetic elements at every hour were paid to the desirability that the arithmetic mean of the five dates should agree with the middle of the month. In some of the other observatories the routine measurement of the curves was continued for several years, but the diurnal inequalities were derived regularly from the quiet days alone and also from all the days of the month, excluding those of large disturbance. If a quiet day differed from an ordinary day only in that the diurnal variation in the latter was partly obscured by irregular disturbances, then such a corresponding day was taken as representing the area included between the curve, the base line and ordinates at the thirteenth minutes before and after each hour.

5. The intensity and direction of the resultant magnetic force at a spot—i.e., the force experienced by a unit magnetic pole—are known if we know the three components of force parallel to any set of orthogonal axes. It is usual to take for these axes the horizontal and vertical axes in the horizontal plane, the latter being usually taken in and perpendicular to the geographical meridian. The usual notation in mathematical work is $X$ to the north, $Y$ to the west, and $Z$ vertically downwards. The $X$ and $Y$ axes are then those of the horizontal plane, and are the axes normally used in mensuration, while $Z$ is taken positive to the east, but the fact that the declination is westerly over most of Europe has often led to the opposite procedure, and writers are not always as careful as they should be in stating their choice. Apart from mathematical calculations, the more usual notation is $X$ and $Y$ for the horizontal and vertical component respectively, and $Z$ for the declination. The horizontal component makes with the astronomical meridian. The declination is sometimes counted from $0^\circ$ to $360^\circ$, $0^\circ$ answering to the case when the so-called north pole (or south-seeking pole) is directed towards geographical north, $90^\circ$ to the case when it is directed to the east, and so on. It is more usual, however, to reckon declination only from $0^\circ$ to $180^\circ$, characterizing it as easterly or westerly according to whether it points to the east or to the west of the geographical meridian. The force is also completely defined by $H$ or $V$, together with $D$ the declination, and $I$ the inclination to the horizon of the dip needle. Instead of $H$ and $D$ some writers use $N$ the northerly component, and $W$ the westerly (or easterly). The resultant force itself is denoted sometimes by $R$, sometimes by $T$ (total force). The following relationships exist between the symbols:

$$X = N, Y = W = 0, Z = V, R = T,$$

$$H = \sqrt{(X^2 + Y^2)}, V = \sqrt{(X^2 + Y^2 + Z^2)},$$

$$\tan D = Y/X, \tan I = V/H.$$
MAGNETISM, TERRESTRIAL

The usual method of conveying information as to the value of the declination at different parts of the earth's surface is to draw curves on a map—the so-called isogonals—such that at all points on any one curve the declination at a given specified epoch has the same value. The information being of special use to sailors, the preparation of magnetic charts has been largely the work of naval authorities—more especially of the hydrographic department of the British admiralty. The object of the admiralty world charts—four of which are reproduced here, on a reduced scale, by the kind permission of the Hydrographer—is rather to show the general features boldly than to indicate minute details. Apart from the immediate necessities of the case, this is a counsel of prudence. The observations used have mostly been taken at dates considerably anterior to that to which the chart is intended to apply. What the sailor wants is the declination now or for the next few years, not what it was five, ten or twenty years ago. Reliable secular change data, for reasons already indicated, are mainly obtainable from fixed observatories, and not from hydrographic charts. Therefore, if we are provided we select an isogonal chart, preferably a map of 1807, that is, a map for the epoch 1807, and if we travel along an isogonal, starting from the north magnetic pole, our course will generally take us, very often circuitously, to the north geographical pole. If, for example, we select the isogonal of 1807, we at first travel nearly south, but then more and more westerly, then north-westerly across the north-east of Asia; the direction then gets less northerly, and makes a dip to the south before finally making for the north geographical pole. It is possible, however, according to the chart, to travel direct from the north magnetic pole to a small westerly or easterly declination (from about 19° W. to 7° E.).

Special interest attaches to the isogonals answering to declination 0°. These are termed agonic lines, but sailors often call them *lines of no variation*, the term variation having at one time been in common use in the sense of declination. If we start from the north magnetic pole the agonic line takes us across Canada, the United States and South America in a fairly straight course to the south geographical pole. A curve continuous with this can be drawn from the south

somewhat limited, but the general nature of the phenomena is easily inferred. The geographical and the magnetic poles—where the dipping needle is vertical—are fundamental points. The north magnetic pole is situated in North America near the edge of the chart. We have no reason to suppose that the magnetic pole is really a fixed point, but for our present purpose we regard it as such. Let us draw an imaginary circle round it, and let us travel round the circle in the direction, west, north, east, south, starting from a point where the north pole of a magnet (i.e. the pole which in Europe or the United States points to the north) is directed exactly towards the geographical pole. The point we start from is to the geographical south of the magnetic pole. As we go round the circle the needle keeps directed to the magnetic pole, and so points first slightly to the east of geographical north, then more and more to the east, then directly east, then to south of east, then to due south, to west of south, to west, to north-west, and finally when we get round to our original position due north once more. Thus, during our course round the circle the needle will have pointed in all possible directions. In other words, isogonals answering to all possible values of the declination have their origin in the north magnetic pole. The same remark applies of course to the south magnetic pole.

Now, suppose ourselves at the north geographical pole of the earth. Neglecting as before diurnal variation and similar temporary changes, and assuming no abnormal local disturbance, the compass needle at and very close to this pole will occupy a fixed direction relative to the ground underneath. Let us draw on the ground through the pole a straight line parallel to the direction taken there by the compass needle, and let us carry a compass needle round a small circle
geographical to the south magnetic pole at every point of which the needle points in the geographical meridian; but here the north pole of the needle is pointing south, not north, so that this portion of curve is really an isogonal of 180°. In continuation of this there emanates from the south magnetic pole a second isogonal of 0°, or agonic line, which traverses Australia, Arabia and Russia, and takes us to the north geographical pole. Finally, we have an isogonal of 180° continuous with this second isogonal of 0° which takes us to the north magnetic pole, from which we started. Throughout the whole area included within these isogonals of 0° and 180°—excluding locally disturbed areas—the declination is westerly; outside this area the declination is in general easterly. There is, however, as shown in the chart, an isogonal of 0° enclosing an area in eastern Asia inside which the declination is westerly though small.

§ 7. Fig. 2 is a reduced copy of the admiralty chart of inclination or dip for the epoch 1807. The places where the dip has the same value lie on curves called *isoclinals*. The dip is northerly (north pole dips) or southerly (south pole dips) according as the place is north or south of the isoclinal of 0°. At places actually on this isoclinal the dipping needle is horizontal. The isoclinal of 0° is nowhere very far from the geographical equator, but lies to the north of it in Asia and Africa, and to the south of it in South America. As we travel north from the isoclinal of 0° along the meridian containing the magnetic pole the dipping needle's north pole dips more and more, until when we reach the magnetic pole the needle is vertical. Going still further north, we have the dip diminishing. The northerly inclination is considerably less in Europe than in the same latitudes of North America; and corresponding

![Fig. 1.—Isogonals, or lines of equal magnetic declination.](chart)
MAGNETISM, TERRESTRIAL

the southerly inclination is less in South America than in the same latitudes of Africa.

Fig. 3 is a reduced copy of the admiralty horizontal force chart for 1907. The curves, called isomagnetics, connect the places where the horizontal force has the same value; the force is expressed in C.G.S. units. The horizontal force vanishes of course at the magnetic poles. The chart shows a maximum value of between 0.39 and 0.40 in an oval including the south of Siam and the China Sea. The horizontal force is smaller in North America than in corresponding latitudes in Europe.

Charts are sometimes drawn for other magnetic elements, especially vertical force (fig. 4) and total force. The isomagnetic of zero vertical force coincides necessarily with that of zero dip, and there is in general considerable resemblance between the forms of lines of equal vertical force and those of equal dip. The highest values of the vertical force occur in areas surrounding the magnetic poles, and are fully 50% larger than the largest values of the horizontal force. The total force is least in equatorial regions, where values slightly under 0.4 C.G.S. are encountered. In the northern hemisphere there are two distinct maxima of total force. One of these so-called foci is in Canada, the other in the north-east of Siberia, the former having the higher value of the force. There are, however, higher values of the total force than at either of these foci throughout a considerable area to the south of Australia. In the northern hemisphere the lines of equal total force—called isodynamic lines—form two sets more or less distinct, consisting of closed ovals, one set surrounding the Canadian the other the Siberian focus.

§ 8. As already explained, magnetic charts for the world or for large areas give only a general idea of the values of the elements. If the region is undisturbed, very fairly approximate values are derivable from the charts, but when the highest accuracy is necessary the only thing to do is to observe at the precise spot. In disturbed areas local values often depart somewhat widely from what one would infer from the chart, and occasionally there are large differences.
MAGNETISM, TERRESTRIAL

between places only a few miles apart. Magnetic observatories usually publish the mean value for the year of their magnetic elements. It has been customary for many years to collect and publish these results in the annual report of the Observatory Department of the National Physical Laboratory. The data in Tables I. and II. are mainly derived from this source. The observatories are arranged in order of latitude, and their geographical coordinates are given in Table II., longitude being reckoned from Greenwich. Table I. gives the mean values of the declination, inclination and horizontal force for January 1, 1901; they are in the main arithmetic means of the mean annual values for the two years 1900 and 1901. The mean annual secular changes given in this table are derived from a short period of years—usually 1898 to 1903—the centre of which fell east all over Europe, and the rate at which it is moving seems not to vary much throughout the continent. The needle is also moving to the west throughout the western parts of Asia, the north and east of Africa, and the east of North America. It is moving to the west in the west of North America, in South America, and in the south and east of Asia, including Japan, south-east Siberia, eastern China and most of India.

§ 9. The information in figs. 1, 2, 3 and 4 and in Tables I. and II. applies to recent and continuous secular change, but there are cases where the change is derived from earlier observations, and the results are given in tables I. and II. Because the earlier observations are not continuous, the change is derived from a short period of years—usually 1898 to 1903—the centre of which fell east all over Europe, and the rate at which it is moving seems not to vary much throughout the continent. The needle is also moving to the west throughout the western parts of Asia, the north and east of Africa, and the east of North America. It is moving to the west in the west of North America, in South America, and in the south and east of Asia, including Japan, south-east Siberia, eastern China and most of India.

at the beginning of 1901. Table II. is similar to Table I., but includes vertical force results; it is more extensive and contains more recent data. In it the number of years is specified from which the mean secular change is derived; in all cases the last year of the period employed was that to which the absolute values assigned to the element belong. The great majority of the stations have declination west and inclination north; it has thus been convenient to attach the + sign to increasing westerly (or decreasing easterly) declination and to increasing northerly (or decreasing southerly) inclination. In other words, in the case of the declination + means that the north end of the needle is moving to the west, while in the case of the inclination + means that the north end (whether the dipping end or not) is moving towards the nadir. In the case, however, of the vertical force + means simply numerical increase, irrespective of whether the north or the south pole dips. The unit employed in the horizontal and vertical force secular changes is 1 y, i.e. 0-00001 C.G.S. For the Kew Observatory, at the very best observation, it is hardly safe to assume that the apparent change from one year to the next is absolutely truthful to nature. This is especially the case if there has been any change of instrument or observer, or if any alteration has been made to buildings in the immediate vicinity. A change of instrument is a much greater source of uncertainty in the case of horizontal force or dip than in the case of declination, and dip circles and needles are more liable to deterioration than magnetometers. Thus, secular change data for inclination and vertical force are the least reliable. The uncertainties, of course, are much less, from a purely mathematical standpoint, for secular changes representing a mean of five or ten years than for those derived from successive years' values of the elements. The longer, however, the period of years, the greater is the chance that one of the elements may in the course of it have passed through a maximum or minimum value. This possibility should always be borne in mind in cases where a mean secular change appears exceptionally small.

As Tables I. and II. show, the declination needle is moving to the

also data for the Indian Ocean and part of the Pacific. These charts showed the isogonic lines, but only over the ocean areas. Though the charts for 1700 were the first published, there are others which apply to earlier epochs. W. van Beemen's maps published charts for the epochs 1500, 1550, 1600, 1650 and 1700, while H. Fritsche has more recently published charts of declination, inclination and horizontal force for 1600, 1700, 1750, 1842 and 1915. A number of early declination charts were given in Hansteen's Atlas and in C. Helmholtz's memoirs. J. Bauer, in the Karten der Isoklinen, Isolinen, Isodynamen (Berlin, 1895). The data for the earlier epochs, especially those prior to 1700, are meagre, and in many cases probably of indifferent accuracy, so that the reliability of the charts for these epochs is somewhat open to doubt.

If we take either Hansteen's or Fritsche's declination chart for 1600 we notice a profound difference from fig. 1. In 1600 the isogonic line starting from the north magnetic pole, after finding its way south along the north American coast, doubled back to the north-east, and passed across or near Iceland. After getting well to the north of Iceland it doubled again to the south, passing to the east of the Baltic. The second isogonic line which now lies to the west of St Petersburg appears in 1800 to have continued, after traversing Australia, in a northerly direction through the extreme east of China. The nature of the changes in declination in western Europe will be understood from Table III., the data from which, though derived from a variety of places in the south-east of England, may be regarded as approximately true of London. The earliest result is that obtained by Bouma at Limehouse. Those made in the 16th century are due to Gunter, Gellibrand, Henry Bond and Halley. The observations from 1757 to 1805 were due to George Gilpin, who published particulars of his own and the earlier observations in the Phil. Trans. for 1806. The data for 1817 and 1820 were obtained by Col. Mark Beaufort, at Bushey, Herts. They seem to come precisely at the time when the needle, which had been continuously moving to the west since the earliest observations, began to retrace its steps. The data from 1860 onwards apply to Kew.

</table>

The rate of movement of the needle at the east towards London—and throughout Europe generally—fell off markedly subsequent to 1880. The change of declination in fact between 1880 and 1895 was only about 75% of that between 1865 and 1880, and the mean annual change from 1895 to 1900 was about 1/4 of the mean annual change of the preceding fifteen years. Thus in 1900 it was at least open to doubt whether a change in the sign of the secular change was anticipated. Subsequent, however, to that date there was little further decline in the rate of secular change, and since 1905 there has been very distinct acceleration. Thus we find that the mean value of the fifteen European stations for which declarations are given in Tables I. and II. we find

mean value from Table I. -4·18

Thus in Table II. we find

mean value -5·21

The epoch to which the data in Table II. refer is somewhat variable, but is in all cases more recent than the epoch, January 1, 1901, for Table I., the mean difference being about 5 years.

10. At Paris there seems to have been a maximum of easterly declination (about 9°) about 1800; it was pointed to true north about 1862, and reached its extreme westerly position between 1812 and 1814. The phenomena at Rome resembled those at Paris and London, but the extreme westerly position is believed to have been attained earlier. The rate of change near the turning point seems to have been very slow, and no fixed observatories existed in those days, the precise time of its occurrence is open to some doubt.

Perhaps the most complete observations extant as to the declination phenomena are those made at Kola Observatory by T. N. Moore; they were given originally by N. A. F. M. Moons, the director of the observatory. Some of the more interesting details are given in Table IV.; here W denotes movement to west, and S to east, and in this treatment, which is easterly.

Prior to 1880 the secular change at Kola was extremely APRIL 1870. The rate of secular change has increased fairly steadily since the turning point was reached.

Table V. contains some data for St. Helena and the Cape of Good Hope, both places having a long magnetic history. The remarkable feature at St. Helena is the uniformity in the rate of secular change. The figures for the Cape show a reversal in the direction of the secular change about 1840, but after a few years the annual rate of change again became visible. According, however, to J. C. Beattie’s Magnetic Survey of South Africa the movement to the west ceased shortly after 1870. A persistent movement to the east then set in, the mean rate of change increasing from 1.8° between 1873 and 1890 to 3.8° between 1890 and 1900.

11. Secular changes of declination have been partially investigated in the United States, although the character to which which is usually complete, thanks to the publications and observations of the United States Coast and Geodetic Survey. At present the secular line passes in a south-easterly direction from the extreme western states to South Carolina. To the east the secular line is westerly, and to the west it is easterly. In 1905 the declination varied from about 21° W. in the extreme north-east to about 15° E. in the south-west. At present the mean rate of the line seems to be towards the west, but it is very slow.

The data in Table VI. represent the mean value of declination per annum, derived from the period (ten years, except for 1900-1905 which ended in the year put at the foot of the column) from the beginning of the present century to 1902. These data indicate that the easterly movement of the magnet, visible in all the earlier figures for the Eastern States in Table VI., existed in all of them at least as far back as 1700. There is not much evidence of the change between 1700 and 1650, the earliest date to which the Coast and Geodetic Survey’s figures refer. The figures show a maximum of westerly declination about 1670 in New Jersey and about 1675 in Maryland. They show that the magnetic needle experienced all along the Atlantic border some time in the 17th century, but earlier in the extreme north-east than in New York or neighboring states.

Examination of Table VI. shows that the needle continued to move to east for some time after 1750 even in the Eastern States. The needle was moving west, and about 1765 the extreme easterly position was reached in Eastport, Maine, the needle then beginning to retrace its steps to the west. The phenomena visible at Maine are seen repeating themselves at present, and moving west more rapidly than the earlier data. The figures for the coast of Maryland are those for about 1600, in Washington, D.C., about 1800, in Columbus (Ohio) about 1815, in Montgomery (Alabama) about 1825, in Bloomington (Ill.) about 1830, in Des Moines (Iowa) about 1840, in Santa Rosa (New Mexico) about 1850, in the Gulf of Mexico about 1865, and the needle was moving west over the whole United States with the exception of a comparatively narrow strip along the Pacific coast.

Even an acute observer would have been tempted to prophesy in 1870 that the needle would move west for many years, and then proceed on a westerly course, according to a purely easterly movement as in the eastern states, but perceptibly slackened. In 1905 the area throughout which the movement to the west still continued had greatly contracted and lay to the east of a line drawn from the west end of Lake Superior to the west of Georgia. If we take a station like Little Rock (Arkansas), we have the secular change to the

West lasting for about sixty years. Further west the period shortens.

At Pueblo (Colorado) it is about forty years, at Salt Lake under thirty years, at Prescott (Arizona) about twenty years. Considering how fast the area throughout which the secular change has been extended to the east since 1855, one would be tempted to infer that at no earlier date it would include the whole of the United States. In the extreme north-east, however, the movement of the needle to the west, which had slackened perceptibly after 1860 or 1870, is once more accelerating. Thus the aperiods do not all point in one, and this future is as uncertain as it is interesting.

§ 12. Table VII gives particulars of the secular change of horizontal force and northerly inclination at London. Prior to the middle of the 18th century, as far as the value of H is of uniform value, the earlier British observations are due to Norman, Gilbert, Bond, Graham, Habeber, and Gilpin. The data from 1857 onwards, both for H and I, refer to Kew. “London” is rather a vague term, but the differences between the values of H and I at Kew and Greenwich—in the extreme west and east—are almost nil. For some time after its discovery by Robert Norman, inclination at London increased. The earlier observations are not sufficient to admit of the date of the maximum inclination or its absolute value being determined with precision. Probably the date was near 1723. This view is supported by the fact that at Paris the inclination fell from 22° 15' in 1754 to 7° 48' in 1780. The

</table>
earlier observations in London were probably of no very high accuracy, and the rates of secular change deducible from them are correspondingly uncertain. It is not improbable that the average annual change 0'8 derived from the thirteen years 1773-1786 is too small, and the various 0'2 derived from the fifteen years 1780-1801 too large. There is, however, other evidence of unusually rapid secular change of inclination towards the end of the 18th century in western Europe; for observations in Paris show a fall of 56' between 1780 and 1791, and of 90' between 1791 and 1806. Between 1801 and 1901 inclination in London diminished by 3° 26'5, or on the average by 2°11 per annum, while between 1857 and 1900 H increased on the average by 227 a year. These values differ little from the secular changes given in Table I as applying for Kew for the epoch Jan. 1, 1901. Since the beginning, however, of the 20th century a notable change has set in, which seems shared by the whole of western Europe. This is shown in a striking fashion by contrasting the data from European stations in Tables I and II. There are fifteen of these stations which give secular change data for H in both tables, while thirteen give secular data for I. The mean values of the secular changes derived from these stations are as follows:

From Table I. \( -2'35 \) +21'0y
From Table II. \( -1'12 \) +1'6y

The difference in epoch between the two sets of results is only about 5 years, and yet in that short time the mean rate of annual inclination in Table I fell to a thirteenth of its original value. During 1808-1900 H diminished throughout all Europe except in the extreme west. Whether we have to do with merely a temporary phase, or whether a general and persistent diminution in the value of H is ascribed to a change in the dipole moment in the earth is yet hardly possible to say.

§ 13. It is often convenient to obtain a formula to express the mean annual change of an element during a given period throughout an area of some size. The usual method is to assume that the change at a place whose latitude is \( \lambda \) and longitude \( \lambda \) is given by an expression of the type \( c + a(l-l_0) + b(\lambda-\lambda_0) \), where \( a, b, c \) are constants, \( l_0 \) and \( \lambda_0 \) denoting some fixed latitude and longitude which it is convenient to take as point of departure. Supposing observational data available from a series of stations throughout the area, \( a, b, c \) can be determined by least squares. As an example, we may take the following slightly modified formula given by Ad. Schmidt as applicable to Northern Europe for the period 1890 to 1900. \( \Delta D \), \( \Delta I \) and \( \Delta H \) represent the mean annual changes during this period in westerly declination, in inclination and in horizontal force:

\[
\Delta D = -5'24 + 0'071(l-50) + 0'033(\lambda-10) \\
\Delta I = -1'08 + 0'010(l-50) + 0'026(\lambda-10) \\
\Delta H = +23'5 - 0'59(l-50) - 0'35(\lambda-10) 
\]

Longitude \( \lambda \) is here counted positive to the east. The central position assumed here (lat. 50°, long. 10° E.) falls in the north of Bavaria. In the case of the horizontal force unity represents 17. Schmidt found the above formulae to give results in very close agreement with the data at the eight stations which he had employed in determining the constants. These stations ranged from Pavlovsk to Perpigean, and from Stonyhurst to Ekaterinburg in Siberia. Formulae involving the second as well as the first powers of \( l-l_0 \) and \( \lambda-\lambda_0 \) have also been used, e.g., by A. Tanakadate in the Magnetic Survey of Japan.

Formulae are also wanted to show how the value of an element, or the rate of change of an element, at a particular place has varied throughout a long period. For comparatively short periods it is best to use formulae of the type \( E = a + b \sin(mt+n) \), where \( E \) denotes the value of an element \( t \) years subsequent to some convenient epoch; \( a, b, c \) are constants to be determined from the observational data. For longer periods formulae of the type \( E = a + b \sin(mt+n) \), where \( a, b, m, n \) are constants, have been used by Schott \(^1\) and others with considerable success. The following examples, due to G. W. Littlehales, \(^2\) for the Cape of Good Hope, will suffice for illustration:

Declination (West) = \( 14^\circ 63' + 15^\circ 00' \sin(60 - t) + 77^\circ 8' \)

Inclination (South) = \( 49^\circ 11' + 8^\circ 75' \sin(60 - t) + 34^\circ 3' \).

Here \( t \) denotes the date. It is perhaps hardly necessary to point out that the extension of any of these empirical formulae—whether to places outside the surveyed area, or times not included in the period of observation—is fraught with danger, which increases rapidly the further the extra-polation is pushed.

Bauer has employed a convenient graphical method of illustrating secular change. Radii are drawn from the centre of a sphere, parallel to the direction of the freely dipping needle, and are produced to intersect the tangent plane at right angles. The points of intersection answers to the mean position of the needle during the epoch under consideration. The curve formed by the points of intersection shows the character of the secular change. Fig. 5 (slightly modified from Nature, vol. 57, p. 181) applies to London. The curve is being described in the clockwise direction. This, according to Bauer's \(^3\) own investigation, is the normal mode of description. Schott and Littlehales have found, however, a considerable number of cases where it is difficult to say whether the motion is clockwise or not, while in some a motion both of the north and south of the Pacific it was clearly anti-clockwise. Fritsch \(^4\) dealing with the secular changes from 1600 to 1885—as given by his calculated values of the magnetic elements—at 204 points of intersection of constant latitudes of 30° north and 30° south, found only sixty-three cases in which the motion was unmistakably clockwise, while in twenty-one cases it was clearly the opposite.

§14. All the magnetic elements at any ordinary station show a regular variation in the annual day. To separate this from the irregular changes, means of the hourly readings must be formed making use of a number of days. The amplitude of the diurnal change usually varies considerably with the epoch of the year. The maximum amplitudes derive from all the days of the year combined, or from a smaller number of days selected equally from all the months of the year, can give only the average effect throughout the year. Also unless the hours of maxima and minima at a given station are but slightly variable with the season, the result obtained by combining data from all the months of the year may be a hybrid which does not very closely resemble the phenomena in the major periods of individual months. This remark applies in particular to the declination at places within the tropics. One consequence of this is that it is necessary to make the range of the diurnal inequality which answers to the year as a whole less than the arithmetic mean of the twelve ranges obtained for the constituent months. At stations in immediate vicinity of these variations, the diurnal inequalities for different months of the year, the difference is mainly one of amplitude, and the mean diurnal inequality from all the months of the year gives a fairly good idea of the nature of the phenomena at the given month.

Table VIII to XI, give mean diurnal inequalities derived from all the months of the year combined, the figures representing the algebraic excess of the hourly value over the mean for the twenty-four hours. The columns in Table III are condensed in Table IV, the hours of which are numbered from 0 to 24. The letter "a" denotes that any hour has been included except as a rule, those characterized by specially large disturbances. The letter "q" denotes that the results are derived from a limited number of days selected as being specially quiet, the results on which they are based on sound evidence.

**MAGNETISM, TERRESTRIAL**

i.e. free from disturbance. In all cases the aperiodic or non-cyclic element—indicated by a difference between the values found for the first and second middnights of the day—has been eliminated in the usual way, i.e. by treating it as accumulating at a uniform rate throughout the twenty-four hours. The years from which the data were derived are indicated. The algebraically greatest and least of the hourly values are printed in heavy type; the range thence derived is given at the foot of the tables.

When comparing results from different stations, it must be remembered that the disturbing forces required to cause a change of 1° in declination and in dip vary directly, the former as the horizontal force, the latter as the total force. Near a magnetic pole the horizontal force is relatively very small, and this accounts

at least partly, for the difference between the declination phenomena at Jan-Mayen and South Victoria Land on the one hand and Kola, Batavia and Mauritius on the other. There is, however, another cause, already alluded to, viz. the variability in the type of the diurnal inequality in tropical stations. With a view to illustrating this point Table XII gives diurnal inequalities of declination for June and December for a number of stations lying between 45° N. and 45° S. latitude. Some of the results are represented graphically in fig. 6, plus ordinates representing westerly deflection. At the northermost station, Tororo, the difference between the two months is mainly a matter of amplitude, the range being much larger at midsummer than at midwinter. The conspicuous phenomenon at both seasons is the rapid swing to the west from 8 or 9 a.m. to

</table>

1 or 2 p.m. At the extreme southern station, Hobart—at nearly equal latitude—the rapid diurnal movement is to the east, and so in the opposite direction to that in the northern hemisphere; whereas in December the inequality at these stations resembles that of temperate regions in the southern hemisphere.

Comparing the inequalities for June in Table XII. amongst themselves, and those for December amongst themselves, one can trace a gradual transition from the phenomena seen at Toronto to those seen at Hobart. At a tropical station the change from the June to the December type is probably in all cases more or less gradual, but at some stations the transition seems pretty rapid.

§ 15. In the case of the horizontal force there are, as Table IX. shows, two markedly different types of diurnal inequality. In the one type, exemplified by Pavlovsk or Greenwich, the force is below its mean value in the middle of the day; it has a principal minimum about 10 or 11 a.m., and morning and evening maxima, the latter usually the largest. In the other type, exemplified by Kolaba or Batavia, the horizontal force is above its mean in the middle of the day.

</table>
day, and has a maximum about 11 a.m. The second type may be regarded as the tropical type. At tropical stations, such as Kolaba, Batavia, Manila and St Helena, the type is practically the same in summer as in winter, and is the same whether the station is north or south of the equator. Similarly, what we may call the temperate type is seen—with comparatively slight modifications—both in summer and winter at stations such as Greenwich or Pavlovsk. In winter, it is true, the pronounced daily minimum is a little later and the early morning maximum is relatively more important in summer. There is not, of course, in the case of the declination, any essential difference between the phenomena at temperate stations in the northern and southern hemispheres.

FIG. 6.

With diminishing latitude, there is a gradual transition from the temperate to the tropical type of horizontal force diurnal variation, and at stations whose latitude is under 45° there is a very appreciable variation in type with the season. The mean diurnal variation for the year at Tiflis in Table IX, really represents a struggle between the two types, in which, on the whole, the temperate type prevails. If we take the diurnal variations at Tiflis for midsummer and midwinter, we find the former essentially of the temperate, the latter essentially of the tropical type. A similar conflict may be seen in the mean diurnal inequality for the year at the Cape of Good Hope, but there the tropical type on the whole predominates, and it prevails more at midwinter than at midsummer. Toronto and Hobart, though similar in latitude to Tiflis, show a closer approach to the temperate type. Still at both stations the hours during which the force is below its mean value tend to extend back towards midnight, especially at midsummer. The amplitude of the horizontal force range appears less at intermediate stations, such as Tiflis, than at stations in either higher or lower latitudes. There is a very great difference in this respect between the north and the south of India.

§ 16. In the case of the vertical force in higher temperate latitudes—e.g., Pavlovsk for instance—the diurnal inequalities from "all" and from "quiet" days differ somewhat widely in amplitude and slightly even in type. In mean latitudes, e.g., at Tiflis, there is often a well marked double period in the mean diurnal inequality for the whole year; but even at Tiflis this is hardly, if at all, apparent in the monthly mean, except in May and June. At low latitudes, the double period is distinctly seen at Kew and Greenwich, though the evening maximum is always pre-eminent. Speaking generally, the time of the minimum, or principal minimum, varies much less with the season than that of the maximum. At Kew, for instance, one can see the minimum falls between 11 a.m. and noon in almost all the months of the year, but the time of the maximum varies from about 2 p.m. in December to 9 p.m. in July. At Kolaba the time of the minimum is always independent of the season, but there is little evidence of the changes from positive to negative in the forenoon and from negative to positive in the afternoon are some hours later in winter than in summer. At Batavia the diurnal inequality varies very little in type with the season, and there is little evidence of a marked secondary minimum about 6 p.m., almost the same hour as at that at which the maximum for the day is observed in summer.

§ 17. Variations of inclination are connected with those of horizontal and vertical force by the relation

\[ \phi = \phi' \sin(V' - \phi H') \]

Thus in temperate latitudes, where \( V \) is considerably in excess of \( H \), while diurnal changes in \( V \) are usually less than those in \( H \), it is the latter which chiefly dominate the diurnal changes in inclination. When the \( H \) influence prevails, \( I \) has its highest values at hours when \( H \) is least. This explains why the dip is above its mean value during those months when the horizontal force dominant, and why at such times the maximum of the horizontal force changes is much closer to the mean of the horizontal force than it would be, if the magnetic force were the same as dip. At Tiflis, the influence of the magnetic force is often considerable, and the dip is not much below its mean value at midsummer. In July and August, however, the influence of the magnetic force is much less, and the dip is much below its mean value, even during the day, as at Batavia. The influence of the magnetic force is also much less at Tiflis than at stations in either higher or lower latitudes. There is a very great difference in this respect between the north and the south of India.

MAGNETISM, TERRESTRIAL

at the Cape of Good Hope does not differ much from that seen at Batavia. Only a single period is clearly shown. The maximum occurs about 8 or 9 p.m. throughout the year. The time of the minimum is more variable; at midsummer it occurs about 11 a.m., but at midwinter three or four hours later. At Hobart the type varies considerably with the season. In June (midwinter) a double period is visible. The principal minimum occurs about 8 a.m., as at the Cape. But, corresponding to the evening maximum seen at the Cape, there is now only a secondary maximum, the principal maximum occurring about 1 p.m. At midsummer the principal maximum is found—as at Kew or Greenwich—about 10 or 11 a.m., the principal minimum about 4 p.m.

§ 18. Even at tropical stations a considerable seasonal change is usually seen in the amplitude of the diurnal inequality in at least one of the magnetic elements. At stations in Europe, and generally in temperate latitudes, the amplitude varies notably in all the elements. Table XIV. gives particulars of the inequality range of declination derived from hourly readings at selected stations, arranged in order of latitude from north to south. The letters "a" and "q" are used in the same sense as before. At temperate stations in either hemisphere—e.g. Pavlovsk, Greenwich or Hobart—the range is considerably larger in summer than in winter. In northern temperate stations a decided minimum is usually apparent in December. There is, on the other hand, comparatively little variation in the range from April to August. Sometimes, as at Kew and Greenwich, there is at least a suggestion of a secondary minimum at midsummer. Manila and Trivandrum show a transition from the December minimum, characteristic of the northern stations, to the January minimum, characteristic of the southern; there being two conspicuous minima in February or March and in November or October. At St Helen there are two similar minima in May and September, while a third apparently exists in December. It will be noted that the declination carries the characteristic of the time of the year, instead of the season, when at Kew or Greenwich, for which the amplitude of the declination is very small during the winter months.

Table XIV. gives a smaller number of data analogous to those of Table XIII., comprising inequality ranges for horizontal force, vertical force and inclination. In some cases the number of years from which the data were derived seems hardly sufficient to give a smooth annual variation. It should also be noticed that unless the same group of years is employed the data from two stations are not strictly comparable. The differences between the all-day mean vertical force data at Pavlovsk is remarkably pronounced.

The general tendency in all the elements is to show a reduced range at midwinter; but in some cases there is also a distinct reduction in the range at midsummer. This double annual period is particularly well marked at Batavia.

§ 19. When discussing diurnal inequalities it is sometimes convenient to consider the components of the horizontal force in and perpendicular to the astronomical meridian, rather than the horizontal force and declination. If N and W be the components of H to astronomical north and west, and D the westerly declination, N = H cos D, W = H sin D. Thus corresponding small variations in N, W, H and D are connected by the relations:

\[ \delta N = \cos \delta D H - H \sin \delta D, \delta W = \sin \delta D H + H \cos \delta D. \]

If \( \delta H \) and \( \delta D \) denote the departures of H and D at any hour of the day from their mean values, then \( \delta N \) and \( \delta W \) represent the corresponding departures of N and W from their mean values. In this way diurnal inequalities may be calculated for N and W when H is known. The formulae supposed \( \delta D \) to be expressed in absolute measure, i.e. \( \delta H \) of arc has to be replaced by 0-0000909. If we take as an example a station at which \( H = 8^5 \) then \( \delta D = 000909 \) (number of minutes in \( \delta D \)). In other words, employing \( \delta H \) as unit of force, one replaces \( \delta D \) by \( 5^8 \delta D \), where \( \delta D \) represents declination change expressed as usual in minutes of arc. In calculating diurnal inequalities for N and W, one ought, strictly speaking, to assign to H and D the exact mean values belonging to the mean for the month or the year being dealt with. For practical purposes, however, a slight departure from the true mean values is immaterial, and one can make use of a constant value for several successive years without sensible error. As an example, Table XV. gives the mean diurnal inequality for the whole year in N and W at Falmouth, as calculated from the 12 years 1891 to 1902. The unit employed is 1y.

Table XIV. gives the diurnal range for the month of July, and the results are such as would be obtained from Table XVI., which is based on the 12 years as Table XV.

Diurnal inequalities in N and W lend themselves readily to the construction of what are known as vector diagrams. These are curves showing the variation of the elements as a function of the hour of the day, the lines joining the points of the graph giving the extent and direction of the horizontal component of the disturbing force to which the diurnal inequality may be regarded as due. Figs. 7 and 8, taken from the Phil. Trans. vol. 204A, will serve as examples. They refer to the mean diurnal inequalities for the month of July at Kew (1890 to 1900) and Falmouth (1890 to 1902), thick lines relating to Kew, thin to Falmouth. NS and EW represent the geographical north-south and east-west directions; their intersection answers to the origin (the line for Kew, thin for Falmouth). The line from the origin to M represents the magnetic meridian. The line from the origin to any cross—the number indicating the corresponding hour counted from midnight as o—represents the magnitude and direction at that hour of the horizontal component of the disturbing force to which the diurnal inequality may be assigned. The cross marks the points whose rectangular co-ordinates are the values of \( \delta N \) and \( \delta W \) derived from the diurnal inequalities of these elements. In Figs. 7 and 8 the distances of the points N, E, S, W from the origin are the inclinations of the lines joining these points to the horizontal.

</table>

In both forms $t$ denotes time, counted usually from midnight, one hour of time being interpreted as $15^\circ$ of angle. Form (i) is that utilized in actual calculating, the constants $b_1, b_2, \ldots$ are used. The $c, a, \ldots$ in the formula:

\[ \tan a_0 = a_0/b_0; \quad c_0 = c_0/b_0; \quad e = e_0; \quad a_0 = c(a_0 + b_0^2). \]

The $a, b, c$ constants are called sometimes Fourier, sometimes Bessel coefficients.

By taking a sufficient number of terms a series can always be obtained which will represent any set of diurnal inequality figures; but unless one can obtain a close approach to the observational figures from the terms possessing the periods 24, 12, 8 and 6 hours the physical significance and general utility of the analysis is somewhat problematical. In the case of the magnetic elements, the 24 and 12 hour terms are usually much the more important; the 24-hour term is generally, but by no means always, the larger of the two. The $c$ constants give the amplitudes of the harmonic terms or waves, the $a$ constants the phase angles. An advance of 1 hour in the time of occurrence of the first (and subsequent, if any) maximum and minimum answers to an increment of $15^\circ$ in $a_0$ of $30^\circ$ in $a_2$, of $45^\circ$ in $a_4$, of $60^\circ$ in $a_6$ and so on. In the case of magnetic elements the phase angles not infrequently possess a somewhat large annual variation. It is thus essential for a minute study of the phenomena at any station to carry out the analysis for the different seasons of the year, and preferably for the individual months. If the $a$ and $b$ constants are known for all the individual months of one year, or for all the Januaries of a series of years, we have only to take their arithmetic means to obtain the corresponding constants for the mean diurnal inequality of the year, or for the diurnal inequality of the average January of the series of years. This, however, is obviously not true of the $c$ or $a$ constants, unless the phase angle is absolutely unchanged throughout the contributory months or years. This is a point requiring careful attention, because when giving values of $c$ and $a$ for the whole year some authorities give the arithmetic mean of the $c$'s and $a$'s calculated from the diurnal inequalities of the individual months of the year, others take the values obtained for $c$ and $a$ from the mean diurnal inequality of the whole year. The former method inevitably supplies a larger value for $c$ than the latter, supposing $a$ to vary with the season. At some observatories, e.g. Greenwich and Batavia, it has long been customary to publish for every year the values of the Fourier coefficients for each month, and to include other elements besides the declination. For a thoroughly satisfactory comparison of different stations, it is necessary to have data from one and the same epoch, and preferably that epoch should include at least one 11-year period. There are, however, a few stations which can supply the data required for such a comparison and we have to make the best of what is available. Information is naturally most copious for the declination. For this element E. Engelenburg gives values of $c_2, c_4, c_6, \ldots$ and of $a_0, a_2, a_4, \ldots$ for each month of the year for about 50 stations, ranging from Fort Rae (62° 6' N. lat.) to Cape Horn (55° 5' S. lat.). From the results for individual stations, Engelenburg derives a series of means which we regard as representative of 11 different zones of latitude. His data for individual stations refer to different epochs, and some are based on only one year's observations. The original observations also differ in reliability; thus the results are of somewhat unequal value. The mean result for Engelenburg's stations must naturally have some of the sources of uncertainty reduced; but then the fundamental idea represented by the arrangement in zones is open to question. The majority of the data in Table XVII. are taken from Engelenburg, but the phase angles have been altered so as to apply to the declination. The stations are arranged in order of latitude from north to south; in a few instances results are given for quiet days. The figures represent in all cases arithmetic means derived from the 12 monthly values. In the table, so far as is known, the local mean time of the observatory has been employed. This is a point requiring attention, because most observatories employ Greenwich time, or time based on Greenwich or some other national observatory, and any departure from local time enters into the values of the constants. The data for Victoria Land refer to the 'Discovery's' 1902-1903 winter quarters, where the declination, taken westward, was 55° 7' on nights of 12-hour term, and so on, taking an hour in f as equivalent to $15^\circ$.

As an example of the significance of the phase angles in Table XVII., take the ordinary day data for Kew. The times of occurrence of the maxima are given by $t + 234° = 45°$ for the 24-hour term, $t + 15° = 90°$ for the 12-hour term, and so on, taking an hour in f as equivalent to $15^\circ$.

Thus the times of the maxima are:

- 24-hour term, 2 h, 24 m. p.m.; 12-hour term, 1 h 41 m. a.m. and 1 h 41 m. p.m.;
- 8-hour term, 4 h, 41 m. a.m., 0 h, 41 m. p.m., and 8 h, 41 m. p.m.;
- 6-hour term, 0 h, 33 m. a.m. and p.m., and 6 h, 33 m. a.m. and p.m.

FIG. 7.

(From Phil. Trans.)
MAGNETISM, TERRESTRIAL

3 68

or extreme easterly positions in the waves, lie midway
between successive maxima. All four terms, it will be seen, have
maxima at some hour between oh. 30m. and 2h. 30m. p.m. They
thus reinforce one another strongly from 1 to 2 p.m., accounting
for the prominence of the maximum in the «arly afternoon.

The minima,

midsummer, in addition to one near midwinter. On the other hand,
the phase angle phenomena vary much for the different elements.
The 24-hour term, for instance, has its maximum earlier in wintet
than in summer in the case of the declination and vertical force,
but the exact reverse holds for the inclination and the horizontal
force.

MAGNETISM, TERRESTRIAL

effects of secular change and annual inequality. Eliminating the secular change, we arrive at an annual inequality, based on all days of the year including the highly disturbed. It is this annual inequality which appears under the heading $s$. It is certainly very unlike the annual inequality derived in the usual way. Whether the difference is to be wholly assigned to the fact that highly disturbed days contribute in the one case, but not in the other, is a question for future research.

In the case of the inclination, Lizar found that in both hemispheres the dip (north in the northern, south in the southern hemisphere) was larger than the normal when the sun was in perihelion, corresponding to an enhanced value of the horizontal force in summer in the northern hemisphere.

In the case of annual inequalities, at least that of the declination, also in the case of the horizontal force—at least in the case of the annual term—both at Kew and Falmouth. The phenomena at the two stations show a remarkably close parallelism. At both, and this is true also of the absolute ranges, the maximum of the annual term falls in all cases near midsummer, the minimum near midwinter. The maxima of the 6-month terms fall near the equinoxes.

§ 24. Allusion has already been made in § 14 to one point which requires fuller discussion. If we take a European station such as Kew, the general tendency, as was found, the declination does not vary very much with the season, but still it does vary. The principal minimum of the day, for instance, occurs from one to two hours earlier in summer than in winter. Let us suppose for a moment that the days of any month are exactly alike, the difference in type between successive months coming in per

**Range**

| $1.42$ | $0.42$ | $0.34$ | $0.95$ | $0.64$ | $1.80$ | $0.65$ | $0.74$ | $1.27$ | $1.33$ | $1.03$ | $0.88$ |

it is somewhat suggestive fact that the range seems to become less as we pass from older to more recent results, or from shorter to longer periods of years. Thus for Paris from 1831 to 1849, the whole range deduced for a range of $2.5^\circ$. Quiet days at Kew from 1890 to 1894 gave a range of $1.7^\circ$, but at Potsdam Ludwig got a range $30^\circ$ larger than that in Table XX, when considering the shorter period 1891-1893. Up to the present, all individual results, if investigated in a very high degree of certainty. With improved instruments and methods it may be different in the future.

**§ 23.** The inequalities in Table XX, may be analysed—as has in fact been done by Hahn—in a series of Fourier terms, whose periods are the year and its submultiples. Fourier series can also be formed representing the annual variation in the amplitudes of the regular diurnal inequality, and its component 24-hour, 12-hour, &c. waves, or of the amplitude of the absolute daily range ($§ 24$). To secure the highest theoretical accuracy, it would be necessary in calculating the Fourier coefficients to allow for the fact that the 'months' from which the observational data are derived are not of uniform length. The mid-times, however, of most months of the year are but slightly displaced from the position they would occupy if the 12 months were exactly equal, and these displacements are usually neglected. The loss of accuracy cannot be but trifling, and the simplification is considerable.

The Fourier series may be represented by

$$ P_i \sin(i \omega + \phi) + P_2 \sin(2i \omega + \phi) + \ldots $$

where $i$ is time counted from the beginning of the year, one month being taken as the equivalent of $30^\circ$, $P_i$ represent the amplitudes, and $\phi_i$ the phases of the Fourier terms, whose periods are respectively 12 and 6 months. Table XXI, gives the values of these coefficients in the case of the range of the regular diurnal inequality for certain specified periods and at Kew $^{b3}$ and Falmouth $^{b3}$ and of the range of the mean diurnal inequality for the range of the 12 months. The letters $q$ and $r$ represent quiet and ordinary day results. $s$ max. means the years 1832-1895, with a mean sun spot frequency of 78°-9; $s$ min. for Kew means the years 1890, 1891, and 1890 with a mean sun spot frequency of 9°-6; for Falmouth it means the years 1899-1902 with a mean sun spot frequency of 7°-25.

Increase in $\phi$ or $\phi_i$ means an earlier occurrence of the maximum or minima, $\phi_i$ answering roughly to one day in the 6-month term, and to half a day in the case of the 6-month term. $P_i$ and $P_2$ both increase decidedly as we pass from years of many to years of few sun spots; i.e. relatively considered the range of the regular diurnal inequality is more variable throughout the year when sun spots are few than when they are many.

The tendency to an earlier occurrence of the maximum as we pass from quiet days to ordinary days, or from years of sun spot minimum to years of sun spot maximum, which appears in the table, appears

| $275^\circ$ | $278^\circ$ | $277^\circ$ | $282^\circ$ | $280^\circ$ | $11.3^\circ$ |

and so on) was $8.4^\circ$, but the range from the whole 4000 odd days superposed was only $8.0^\circ$. Another consideration is this: the absolute range in individual days, i.e. the difference between the algebraically largest and least values of the element found any time during the 24 hours, must on the average exceed the
range in the mean diurnal inequality for the year, however this latter is formed. Other causes, moreover, are at work tending in the same direction. Even in central Europe, the magnetic curves for individual days of an ordinary month often differ widely amongst themselves, and show maxima and minima at different times of the day. In high latitudes, the variation from day to day is sometimes so great that mere eye inspection of magnetograph curves may leave one with but little idea as to the probable shape of the resultant diurnal curve for the month. Table XXII gives the arithmetic mean of the absolute daily ranges from a few stations. The values which it assigns to the year are the arithmetic means of the 12 monthly values. The Mauritius data are for different periods, viz. declination 1875, 1880, and 1883 to 1890, horizontal force 1883 to 1890, vertical force 1884 to 1890. The other data are all for the period 1890 to 1900.

A comparison of the absolute ranges in Table XXII, with the inequality ranges for the same stations derived from Tables VIII. to X. is most instructive. At Mauritius the ratio of the absolute to the inequality range is for D 1:38, for H 1:76, and for V 1:19. At Pavlovsk the corresponding ratios are much larger, viz. 2:16 for D, 2:43 for H, and 2:05 for V. The declination data for Kew in Table XXII. illustrate other points. The first set of data are derived from all days of the year. The second omit the highly disturbed days. The third answer to the 5 days a month selected as typically quiet. The yearly mean absolute range from ordinary days at Kew in Table XXII. is 1:49 times the mean inequality range in Table VIII.; comparing individual months the ratio of the absolute to the inequality range varies from 2:06 in January to 1:21 in June. Even confining ourselves to the quietest days at Kew, which are free from any but the most trifling disturbances, we find that the mean absolute range for the year is 1:20 times the arithmetic mean of the inequality ranges for the individual months of the year, and 1:22 times the range from the mean diurnal inequality for the year. In this case the ratio of the absolute to the inequality range varies from 1:55 in December to only 1:09 in May.

### Notes

25. The variability of the absolute daily range of declination is illustrated by Table XXIII. which contains data for Kew derived from all days of the 11-year period 1890–1900. It gives the total number of times during the 11 years when the absolute range lay within the limits specified at the heads of the first nine columns of figures. The two remaining columns give the arithmetic means of the five largest and the five least absolute ranges encountered each month. The mean of the twelve monthly diurnal inequality ranges from ordinary days was only 8° 44', but the absolute range during the 11 years exceeded 20° on 492 days, 15° on 1196 days, and 10° on 2784 days, i.e. on 69 days out of every 100.

26. Magnetic phenomena, both regular and irregular, at any station vary from year to year. One of the most curious and difficult problems is that of the relative diurnal inequality in the elements stated at the head of the columns. The ordinary day declination data (D,) for Kew represent arithmetic means from the twelve months of the year; the other data all answer to the mean diurnal inequality for the whole year. Table XXV. gives the arithmetic means for each year of the absolute daily range, of the monthly range (or difference between the highest and lowest values in the month), and of the yearly range (or difference between the highest and lowest values of the year). The numbers attached to the years in these tables indicate their order as regards sun-spot frequency according to Wolf and Wolfers (see Aurora Polaris), 1893 being the year of largest frequency, and 1890 that of least. The difference in sun-spot frequency between 1891 and 1895 was 18 per cent; the differences between 1890, 1899 and 1890 were small, and those between 1891, 1894 and 1892 were not very large.

The years 1892–1893 represent high sun-spot frequency, while 1890, 1899 and 1890 represent low frequency. Table XXV. shows that 1892 to 1895 were in all cases distinguished by the large size of the inequality ranges, and 1890, 1899 and 1890 by the small size. The range in 1893 is usually the largest, and though the H and V
ranges at Ekaterinburg are larger in 1892 than in 1893, the excess is trifling. The phenomena apparent in Table XXIV. are fairly representative; other stations and other periods associate large inequality ranges with high sun-spot frequency. The diurnal inequality range it should be noticed is comparatively little influenced by irregular disturbances. Coming to Table XXV., we have ranges of a different character. The absolute range at Kew on quiet days is almost as little influenced by irregularities as is the range of the diurnal inequality, as is the case with the phenomena associated to those observed in Table XXIV. As we pass from left to right in Table XXV., the influence of disturbance increases. Simultaneously with this, the parallelism with sun-spot frequency is less close. The entries relating to 1892 and 1894 become more and more prominent compared to those for 1893. The yearly range may depend on but a single magnetic field of a central month, the object of years past varying far outstripping any other. But taking even the monthly ranges, the values for 1893 are, speaking roughly, only half those for 1892 and 1894, and very similar to those of 1868, though the sun-spot frequency in the latter year was less than a third of that of 1893. Ekaterinburg data exactly analogous to those for Pavlovsk show a similar prominence in 1892 and 1894 as compared to 1893.

1893. The retirement of 1893 from first place, seen in the absolute ranges at Kew, Pavlovsk and Ekaterinburg, is not confused to the northern hemisphere. It is visible, for instance, in the amplitudes of the Batavia disturbance results. Thus though the variation from year to year in the amplitude of the absolute ranges is relatively not less but greater than that of the inequality ranges, and though the general tendency is for all ranges to be larger in years of many than in years of few, the general relation between changes in sun-spot frequency and in magnetic range is not so close for the absolute ranges and for disturbances as for the inequality ranges. 27. The relationship between magnetic ranges and sun-spot frequency has been investigated in several ways. W. H. Ellis has employed a graphical method which has advantages, especially for tracing the general features of the resemblance, and is besides independent of any theoretical hypothesis. Taking time for the axis of abscissae, and 12 months' magnetic range for its ordinates the sun-spot frequency, the other the inequality range of declination or of horizontal force at Greenwich. The value assigned in the magnetic curve to the order for any particular month represents a mean range from 12 months' which it is feared a large monthly partial may be being to eliminate the regular annual variation in the diurnal inequality. The sun-spot data derived from Wolf and Wilber were similarly treated. Ellis originally dealt with the period 1841 to 1877, but subsequently with the period 1878 to 1896, and his second paper gives curves representing the phenomena over the whole 56 years. This period covered five complete sun-spot periods, and the approximate synchronism of the maxima and minima, and the general parallelism of the magnetic and sun-spot changes is patent to the eye. Ellis has also applied an analogous method to investigate the relationship between sun-spot frequency and the number of days of magnetic disturbance at Greenwich. A decline in the number of the larger magnetic storms near sun-spot minimum is recognisable, but the position of the maximum in the case of the inequality range. Another method, initiated by Professor Wolf of Zurich, lends itself more readily to the investigation of numerical relationships. He started by supposing an exact proportionality between corresponding changes in sun-spot frequency and magnetic range. This is expressed mathematically by the formula

\[ R = a + bS \equiv a(1 + (b/a)S) \]

where \( R \) denotes the magnetic range, \( S \) the corresponding sun-spot frequency, while \( a \) and \( b \) are constants. One of the successful of horizontal and vertical force are above criticism. Declination is less exposed to uncertainty, and there are results of eye observations of declination before the era of photographic records. A change, however, in declination is not always accompanied by a change in horizontal force. During the period 1850–1900 horizontal force in England increased about 10%, so that the force requisite to produce a declination of change of 10' in England in 1850 had produced a deflection of 20'. It must also be remembered that secular changes of declination must alter the angle between the needle and any disturbing force acting in a horizontal plane. A deflection of 10' is rather to be anticipated, especially in the case of the declination. Wolf's formula has been applied by Rajna\(^\text{28}\) to the yearly mean diurnal declination ranges at Milan based on readings taken twice daily from 1856 to 1894, treating the whole period together, and then the period 1871 to 1894 separately. During two sub-periods, 1837–1850 and 1854–1871, Rajna's calculated values for the range differ very consistently in one direction from the observed. A range of Wolf's formula was applied by C. Chree\(^\text{29}\) to these two periods separately. He also applied it to Greenwich inequality ranges for the years 1841 to 1896 as published by Ellis, and the whole period and the last 15 years it separately, and finally to all (a) and quiet (q) day Greenwich ranges from 1889 to 1896. The results of these applications of Wolf's formula appear in Table XXVI.

**Table XXVI.—Ranges of \( a \) and \( b \) in Wolf's Formula.**

Wolf's formula has also been applied to the absolute daily ranges, to monthly ranges, and to various measures of disturbance. In these cases the values found for b/a are usually smaller than those found for diurnal inequality ranges, but the accordance between observed values and those calculated from Wolf's formula is less good. If instead of the range of the diurnal inequality we take the sum of the 24-hour differences from the mean for the day—what comes to the same thing, the average departure throughout the 24 hours from the mean value for the day—we find that the results obtained from Wolf's formula gives at least as good an agreement with observation as in the case of the inequality range itself. The formulae obtained in the case of the 24 differences, as placed at wide apart as Kew and Batavia, agree in giving a decidedly larger value for b/a than that obtained from the range of the diurnal inequality. This indicates that the inequality here is relatively less peaked in years of many than in years of few sunspots.

§ 28. The applications of Ellis's and Wolf's methods relate directly only to the amplitudes of the diurnal changes. There is, however, a change not merely in amplitude but in type. This is clearly seen when we compare the values found in years of many and of few sunspots for the Fourier coefficients in the diurnal inequality. Such a comparison is carried out in Table XXVIII. for the years 1875-1880, and the results are seen to be practically identical, whatever the number of sunspots. The sign of the difference in the case of D, I and H was the same in each year examined by Müller, and the same was true of H at Greenwich. In the case of V and D at Greenwich, the differences are

small and might be accidental. In the case of D at Greenwich 1891
differed from the other years, and of two more recent years examined
by Ellis\textsuperscript{31} one, 1904, agreed with 1891. At Kew, on the average of
the 11 years 1890 to 1900, the quiet-day mean annual value of declina-
tion exceeded the ordinary day value, but the apparent excess o°-o2
is too small to be of importance.

Another property more recently discovered in quiet days is the
non-cyclic change. The nature of this phenomenon will be readily
understood from the following data from the 11-year period
1890 to 1900 at Kew.\textsuperscript{8} The mean daily change for all days is calculated from the observed annual change.

Thus the changes during the representative quiet day differed from
those of the average day. Before accepting such a phenomenon as
natural, instrumental peculiarities must be carefully considered.
The secular change is really based on the absolute instruments, the
diurnal changes on the magnetographs, and the first idea likely to
occur to a critical mind is that the apparent abnormal change on quiet
days represents in reality change of zero in the magnetographs.
H, however, the phenomenon was instrumental, it should appear
equally on days other than quiet days, and we should thus have a
shift of zero amounting in a year to over 1,200y in H, and to about 90’ in H.
Under such circumstances the curve would be continually drifting on
the scale mean of the magnetographs. In the case of the Kew magnetographs,
careful investigation showed that if any instrumental change occurred in
the declination magnetograph during the 11 years it did not exceed
a few tenths of a minute. In the case of the H and V magnetographs
at Kew there is a slight drift, of instrumental origin, due to weakening
of the magnets, but it is exceedingly small, and in the case of
H is in the opposite direction to the non-cyclic change on quiet
days. It only remains to add that the hypothesis of instrumental
origin was positively disproved by measurement of the curves on
ordinary days.

It must not be supposed that every quiet day agrees with the aver-
age quiet day in the order of magnitude, or even in the sign, of the
non-cyclic change. In fact, in not a few months the sign of the non-
cyclic change on the mean of the quiet days differs from that
obtained for the average quiet day of a period of years. At
Kew, between 1890 and 1900, the number of months during which
the mean non-cyclic change for the five quiet days selected by the
astronomical director (Sir W. H. M. Christie) was plus, zero, or minus,
as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>D.</th>

</tr>
</tbody>
</table>

The + sign denotes westerly movement in the declination, and in-
creasing size of the north end of the needle. In the case of H
H the excess in the number of months showing the normal sign is
overwhelming. The following mean non-cyclic changes on quiet
days are from other sources:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

The results are in the same direction as at Kew, + meaning in
the case of D movement to the west. At Falmouth\textsuperscript{32}, as at
Kew, the non-cyclic change showed a tendency to be small in years of
sun-spot maximum.

§ 30. In calculating diurnal inequalities from quiet days the non-
cyclic effect must be eliminated, otherwise the result would depend
on the hour at which the day \( \) is supposed to commence. If the
value recorded at the second midnight of the average day exceeds
that at the first midnight by N, the elimination is effected by apply-
ing to each hourly value the correction N(12-n)/24, where n is the
hour counted from the first midnight (0 hours). This assumes
that changes to progress uniformly through the days; this is practically the case—a matter difficult either to prove or
disprove—the correction may not secure exactly what is aimed at.

This method has been employed in the previous tables. The fact
that differences do exist between diurnal inequalities derived from
quiet days and all ordinary days was stated explicitly in § 4, and is
obvious in Tables VIII. to XI. An extreme case is represented by
the data for Jan Mayen in these tables. Figs. 9 and 10 are vector
diagrams for this station, for all and for quiet days during May, June
and July 1883, according to data got out by Lideling. As shown by
the arrows, fig. 10 (quiet days) is in the main described in the
normal or opposite direction, but two (all days) are described in the
opposite direction. Lideling found this peculiar difference
between all and quiet days at all the north polar stations occupied
in 1882–1883 except Kingua Fjord, where both diagrams were
described clockwise.

In temperate latitudes the differences of type are much less, but
still they exist. A good idea of their ordinary size and character
in the zone of declination may be derived from Table XXIX., con-
taining data for Kew, Greenwich and Parc St. Maur.

The data for Greenwich are due to W. Ellis\textsuperscript{33}, those for Parc
St. Maur to T. Moureaux\textsuperscript{4}. The quantity tabulated is the algebraic
excess of the all or ordinary day hourly value over the corre-
spacing quiet-day value in the mean distribution, notably large
at the year. At Greenwich and Kew days of extreme disturbance have
been excluded from the ordinary days, but apparently not at Parc
St. Maur. The number of highly disturbed days at the three stations
is, however, small, and the influence of a day may be noted.

The differences disclosed by Table XXIX. are obviously of a systematic
character, which would not tend to disappear however long a period was
utilized. In short, while the diurnal inequality from quiet days
may be that most truly representative of undisturbed conditions,
it does not represent the average state of conditions at the station.

To go into full details respecting the differences between all and quiet
days would occupy undue space, so the following brief summary of
the differences observed at Greenwich is mentioned.

The inequality range is but little different for the two types of days,
the mean of the hourly differences from the mean for the day is
considerably reduced in the quiet days. The 24-hour term in the
Fourier analysis is of smaller amplitude in the quiet days, and its
maximum is on the 11-year cycle. The range is 6°-75 sum per 24
hours in the ordinary days, implying a retardation of about 27 minutes in the time of maxi-
mum. The diurnal inequality range is more variable throughout
the year in quiet days than on ordinary days, and the same is true of
the annual ranges. The diurnal inequality range for the year in the
range at midsummer is considerably more decided on ordinary than
on quiet days. When the variation throughout the year in the
diurnal inequality range is expressed in Fourier series, whose periods
determine the influence of solar and lunar disturbances, the criteria
employed in selecting quiet days and in excluding disturbed days.
This raises difficulties when it comes to comparing results at different
stations. For stations near together the difficulty is trivial. The
astomical department has found no serious difficulty at Parc
St. Maur, Val Joyeux, Falmouth and Kew, as well as at Greenwich.

But when stations are wide apart there are two obvious difficulties:
first, the difference of local time; secondly, the fact that a day may
typically quiet at one station but appreciably disturbed at the other.

If the typical quiet day were simply the antithesis of a disturbed
day, it would be natural to regard the non-cyclic change on quiet
days as a species of recoil from some effect of disturbance. This
view derives support from the fact, pointed out long ago by Sabine\textsuperscript{4}
that the horizontal force usually, though by no means always, is
lowered by magnetic disturbances. Dr van Bemmelen\textsuperscript{35} who has
examined non-cyclic phenomena at a number of stations, seems
disposed to regard the horizontal change as due in the main to the
are, however, difficulties in accepting this view. Thus, whilst the
non-cyclic effect in horizontal force and inclination at Kew and Falmouth
appeared on the whole enhanced in years of sun-spot maximum,
the diurnal variations between years such as 1892 and 1894 on the one
hand, and 1890 and 1900 on the other, was by no means proportional
to the excess of disturbance in the former years. Again, when the
average non-cyclic change of declination was calculated at Kew for
207 days, selected as those of most marked irregular disturbance
between 1890 and 1900, the sign actually proved to be the same as for
the average quiet day of the period.

§ 31. A satisfactory definition of magnetic disturbance is about as difficult to lay down as one of heterodoxy. The idea in its generality seems to possess no difficulty, but it is a very general definition when one comes to details. Amongst the chief disturbances recorded since 1890 are those of February 13-14 and August 12, 1892, July 20 and August 20, 1894; March 15-16, September 9, 1895; October 3-4, 1902; September 11-12, 1908 and September 25, 1909. In such days as these the oscillations shown by the magnetic curves are large and rapid, aurora is nearly always visible in temperate latitudes, earth currents are prominent, and there is induction...enough to be serious...in the transmission of telegraph messages both in overhead and underground wires. At the other end of the scale are days on which the magnetic curves show practically no movement beyond the slow regular progression of the regular diurnal inequality. But between these two extremes there are an infinite variety of intermediate cases. The first serious attempt at a precise definition of disturbance seems due to General Sabine.

Magnetic Disturbances

His method had the disadvantage of always giving a continuous curve, which made it difficult to apply to some important observatories. Sabine regarded a particular observation as disturbed when it differed from the mean of the observations at that hour for the whole month by not less than a certain limiting value. His definitions count only on the extent of the departure from the mean, whether the curve is smooth or not. In this case, the disturbance is less important because it leaves the curve undisturbed. But even Sabine's definition is not satisfactory as it leaves the curve undisturbed. However, the disturbance is still serious because it is shown by the observations.

Table XXXI shows in some cases a most conspicuous diurnal variation in Sabine's disturbances. The data are percentages of the total values for the entire day.

Table XXXI.-Annual Variation of Disturbances (Sabine's numbers).

</table>

The best results for that station, and Th. Moureau, has published similar data for Paris St Maur. Table XXX, to XXXII, are based on a selection of these data. Tables XXX, and XXXI, show the annual variation of disturbances, the monthly values being expressed as percentages of the arithmetic mean value for the 12 months. The Paris St Maur and Batavia data, owing to the long periods included, are especially noteworthy. Table XXXI deals with the east (E) and west (W) disturbances of declination separately. Table XXXII, dealing with disturbances in horizontal and vertical force, combines + and - disturbances, treated numerically. At Parc St Maur the limits required to qualify for disturbance were 3'0 in D, 20' in H, and 12' in V; the corresponding limits for Batavia were 1'0 and 1'5. The limits for D at Tokyo, Bombay and Hobart were respectively 3'-6', 1'-4' and 2'-4'.

At Parc St Maur the disturbance data from all three elements give disturbances near the equinoxes; a minimum at midwinter is clearly shown, and also one at midsummer, at least in D and H. A decline in disturbance at midwinter is visible at all the stations, but at Batavia the equinoctial values for D and V are inferior to those at midsummer.

Table XXXII shows in some cases a most conspicuous diurnal variation in Sabine's disturbances. The data are percentages of the total values for the entire day. While at Batavia the easterly and westerly disturbances in D vary similarly, at Parc St Maur they follow opposite laws, the easterly showing a prominent maximum near noon, the westerly a still more prominent maximum near midnight. The figures in the second last line of the table, if divided by 24, will give the percentage of hours which show the species of disturbance indicated. At Parc St Maur, out of 105 hours, 3 show disturbances to the west and 3 to the east; or in all 67 show disturbances of declination. The last line gives the average size of a disturbance of each type, the unit being 1' in D and 1' in H and V.

At Batavia disturbances increasing and decreasing the element are about equally numerous, but this is exceptional. Easterly disturbances of declination predominated at Batavia, Point Barrow, Fort Kennedy, and Kew St Maur, Bombay and the Falkland Islands whilst the reverse was true of St Helena, Cape of Good Hope, Pekin and Hobart. At Kew and Parc St Maur the ratios borne by the

eastern to the western disturbances were 1:19 and 1:23 respectively; and so not much in excess of unity; but the preponderance of easterly disturbances at the North American stations was considerably larger than this.

§ 32. From the point of view of the surveyor there is a good deal to be said for Sabine's definition of disturbance, but it is less satisfactory from other standpoints. One objection has been already indicated, viz. the arbitrariness of applying the same limiting value at a station irrespective of the size of the normal diurnal range at the time. Similarly it is arbitrary to apply the same range between 10 a.m. and midnight, when it is hardly appreciable. There seems a distinct difference of phase between the diurnal inequalities on different types of days at the same season; also the phase angles in the Fourier terms vary continuously throughout the year, and much more rapidly at some stations and at some seasons than at others. Thus there may be a variety of phenomena which would hesitate to regard as disturbances which contribute to the annual and diurnal variations in Tables XXX to XXXII.

Since we have seen how Sabine's definition is inattentive to the departure of the hourly reading from the mean for that hour. Another and equally natural criterion is the apparent character of the magnetograph curve. At Potsdam curves are regarded as "1" quiet, "2" moderately disturbed, or "3" highly disturbed. Any hourly value to which the numeral 3 is attached is treated as disturbed, and the annual Potsdam publication contains tables giving the annual and diurnal variations in the number of such disturbed hours for D, H and V. According to this point of view, the extent to which the hourly value departs from the mean for that hour is immaterial to the results. It is the greater or less sinuosity and irregularity of the curve that counts. Tables XXXIII and XXXIV give an abstract of the mean Potsdam results from 1862 to 1901. The data are per minute, and Table XXXIII, of which this is a much smaller and more complex table, is of the total for the day. So far as the annual variation is concerned, the results in Table XXXIII are fairly similar to those in Table XXX, for Parc St Maur. There are pronounced maxima near the equinoxes, especially the spring equinox. The diurnal uncertainty is unlikely to have much influence on the diurnal, or even on the annual variation.

§ 33. A third method of investigating a diurnal period in disturbances is to form a diurnal inequality from disturbed days alone, and compare it with the corresponding inequalities from ordinary or from quiet days. Table XXXV gives some declination data for Kew, the quantity tabulated being the algebraic excess of the diurnal hourly value over that in the ordinary or disturbed day. The inequality for the year, as based on the 11 years 1890 to 1900.

The disturbed day inequality was corrected for non-cyclic change in the usual way. Table XXXV gives the results of Table XXXV, graphically represented, and shows slightly due to the limited number, +4 209, of disturbed days employed; to get a smooth curve would probably require a considerable number of years. The differences between disturbed and ordinary days at Kew are of the same general character and those between ordinary and quiet days in Table XXXIX; they are, however, very much larger, the range in Table XXXIX, being fully 3 times that in Table XXXIX. If quiet day and replaced ordinary day results in Table XXXV, the algebraic excess of the disturbed day would have varied from +2 to -7 at 1 p.m. to -4 to 1 p.m.

§ 34. When the mean diurnal inequality in declination for the year at Kew is analysed into Fourier waves, the chief difference, it will be remembered, between ordinary and quiet days was that the amplitude of the diurnal term was increased, whilst its phase angle indicated an earlier occurrence of the maximum. Similarly, the chief difference between the Fourier waves for the disturbed and ordinary day inequalities at Kew is the increase in the amplitude of the 24-hour term in the former by over 70%, and the earlier occurrence of its maximum by about 1 hour 50 minutes. It is clear from these results for Kew, and it is also a necessary conclusion of a local peculiar behavior, that a probable subject for further research.

§ 35. There are still other ways of attacking the problem of disturbances. W. Ellis's made a complete list of disturbed days at Greenwich giving the times of days in classes according to the amplitude of the disturbance shown on the curves. Of the 18,000 days which he considered, Ellis regarded 2,119, or only about 12%, as undisturbed. On 10,968 days, or 66%, the disturbance movement in declination was under 10%, on 364, or 2%, the disturbance, though exceeding 10%, was under 30%; on 294 days it lay

The Table XXXV shows, however, in Tables XXXII and XXXIV, that the disturbances at Parc St Maur occurred before 6 a.m. and 6 p.m. while in Table XXXV, they occur between 4 p.m. and midnight. Considering the comparative proximity of Parc St Maur and Potsdam, one may conclude that the apparent differences between the results for these two stations are due in almost entirety to the difference in the definition of a disturbed day. One difficulty in the Potsdam procedure is the maintenance of a uniform standard. Unless very frequent reference is made to the definition of a disturbed day, the standard remains uncertain. Still, such a state of affairs suggests a preference for the current method of defining disturbances. It is further suggested that the results for the years 1890 to 1900 may be corrected by the method of Table XXXV, giving the results of Table XXXV, graphically represented, and showing slightly due to the limited number, +4 209, of disturbed days employed; to get a smooth curve would probably require a considerable number of years. The differences between disturbed and ordinary days at Kew are of the same general character as those between ordinary and quiet days in Table XXXIX; they are, however, very much larger, the range in Table XXXIX, being fully 3 times that in Table XXXIX. If quiet day and replaced ordinary day results in Table XXXV, the algebraic excess of the disturbed day would have varied from +2 to -7 at 1 p.m. to -4 to 1 p.m. When the mean diurnal inequality in declination for the year at Kew is analysed into Fourier waves, the chief difference, it will be remembered, between ordinary and quiet days was that the amplitude of the diurnal term was increased, whilst its phase angle indicated an earlier occurrence of the maximum. Similarly, the chief difference between the Fourier waves for the disturbed and ordinary day inequalities at Kew is the increase in the amplitude of the 24-hour term in the former by over 70%, and the earlier occurrence of its maximum by about 1 hour 50 minutes. It is clear from these results for Kew, and it is also a necessary conclusion of a local peculiar behavior, that a probable subject for further research.

§ 35. There are still other ways of attacking the problem of disturbances. W. Ellis's made a complete list of disturbed days at Greenwich giving the times of days in classes according to the amplitude of the disturbance shown on the curves. Of the 18,000 days which he considered, Ellis regarded 2,119, or only about 12%, as undisturbed. On 10,968 days, or 66%, the disturbance movement in declination was under 10%, on 364, or 2%, the disturbance, though exceeding 10%, was under 30%; on 294 days it lay...
between 30° and 60°; while on 75 days it exceeded 60°. Taking each class of disturbances separately, Ellis found, except in the case of his "minor" disturbances—those under 10°—a distinct double annual period, with maxima towards the equinoxes. Subsequently C. W. van Bemmelen, using the same data, and of subsequent data up to 1902, put at his disposal by Ellis, came to similar conclusions. Taking all the days with disturbances of declination over 10° and dealing with 15-day periods, he found the maxima of frequency at the equinoxes, in the spring being further away. The other apparently is that of the annual minimum, the two minima were found to occur early in June and in January. When the year is divided into two periods—winter (November to February), summer (May to August)—the minima of frequency occur in the disturbances over 60°, but their number is very small that this may be accidental. The chief criterion at Kew for classifying the days was not so much the mere amplitude of the largest movement, as the general character of the daily curve and its departure from an average form. The table in Table XXXVI, as magnetic storms at Greenwich are based on the lists given by Maunder in the Monthly Notices, R.A.S. A storm may last for any time from a few hours to several days, and during part of its duration the disturbance may not be very large; thus it may not necessarily follow that the frequency of magnetic storms and of disturbed days will follow the same laws. The table shows, however, that so far as Greenwich is concerned the annual variations in the two cases are closely alike. In addition to mean data for the whole year, 1848 to 1903, Table XXXVI gives the daily and monthly means of the 14 years of that period which represented the highest sun-spot frequency, and the 15 years which represented lowest sun-spot frequency. It will be seen that relatively considered the seasonal frequencies of disturbance are much more nearly equal in the years of many than in those of few sun-spots. Storms are more numerous as a whole in the years of many sun-spots, and this preponderance is especially true of storms of the largest size. This requires to be borne in mind in any comparisons between larger and smaller disturbances; and the term "storm" is in the present work used in a general sense to denote any noticeable deviation from normal conditions, however brief. An unduly large proportion of the larger storms will probably come from years of large sun-spot frequency, and there is thus a risk of assigning differences to the laws obeyed by large and small storms. Where selected prominently from a list of disturbances, the disturbances selected promiscuously from a long series of disturbances which have been analyzed will not be affected by this selection.

The last data in Table XXXVI are based on statistics for Batavia given by W. van Bemmelen, who considers separately the storms which were preceded suddenly and those which did not. The sudden movements are recorded over large areas, sometimes probably all over the earth, if not absolutely simultaneously, at least too nearly for differences in the time of occurrence to be shown by ordinary magnetograms. If the sudden movements, and the storms to which they serve as precursors, arise from some source extraneous to the earth, and that the commencement of the movement intimates the arrival, probably in the upper atmosphere, of some form of energy which bathed the earth, the storms which commence gradually the existence of a source external to the earth is not so prominently suggested, and it has been sometimes supposed that there is a fundamental difference between the two classes. Batavia, however, has been at the very core, more than elsewhere, of the annual variation at Batavia. The same time, this possesses much less significance than it would have if Batavia were a station like Greenwich, where the annual variation in magnetic storms is conspicuous.

Besides the annual period, there seems to be also a well-marked diurnal period in magnetic disturbances. This is apparent in Tables XXXVII and XXXVIII, which contain some statistics for Batavia due to van Bemmelen, and some for Greenwich derived from the data given in the earlier papers referred to above. Table XXXVII gives the relative frequency of occurrence for two hour intervals, starting with midnight, treating separately the storms of gradual (g) and sudden (s) commencement. In Table XXXVIII, the day is divided into three equal parts. Both tables and Greenwich agree in showing maximum frequency of beginnings about the time of minimum frequency of endings and conversely, but the hours at which the respective maxima and minima occur at the two places differ rather notably.

§ 36. The principal peculiarities in the sudden movements ushering in magnetic storms which deserve fuller mention. According to van Bemmelen the impulse consists usually at some stations of a sudden slight jerk of the magnet in one direction, followed by a longer decided movement in the opposite direction, the former being distinct, the latter distinctly shown. Often we have at the very commencement but a faint outline, and thereafter a continuous movement which is only sometimes distinctly indicated, resulting after some minutes in the displacement of the trace by a finite amount from the position it occupied on the paper before the disturbance began.

| Table XXXVI.—Disturbances, and their Annual Distribution. |
|------------------|------------------|
|                  | Total Number.    | Percentages. |
| Greenwhich disturbed days, all, 1848-1902 | 4,214 | 33-9 | 39-2 | 26-9 |
| Greenwhich disturbed days, range 10° to 30°, 1848-1902 | 3,850 | 33-9 | 39-0 | 27-1 |
| Greenwhich disturbed days, range 30° to 60°, 1848-1902 | 307 | 34-5 | 41-0 | 24-4 |
| Greenwhich disturbed days, range over 60°, 1848-1902 | 77 | 29-9 | 41-6 | 28-6 |
| Kew highly disturbed days, 1890-1903 | 209 | 38-3 | 41-6 | 20-1 |
| Greenwhich magnetic storms, all, 1848-1903 | 726 | 32-1 | 42-3 | 25-6 |
| Greenwhich magnetic storms, range 20° to 30°, 1848-1903 | 392 | 30-1 | 46-3 | 26-6 |
| Greenwhich magnetic storms, range over 30°, 1848-1903 | 334 | 34-4 | 40-7 | 29-9 |
| Greenwhich magnetic storms, all, 14 years of S. max. | 258 | 35-3 | 38-0 | 20-7 |
| Batavia magnetic storms, all, 1883-1893 | 1,008 | 32-9 | 34-2 | 22-9 |
| Batavia magnetic storms of gradual commencement. | 679 | 32-4 | 34-8 | 28-2 |
| Batavia magnetic storms of sudden commencement. | 329 | 33-7 | 35-3 | 31-0 |

This may mean, as van Bemmelen supposes, a small preliminary movement in the opposite direction to the clearly shown displacement, but it may only mean that the magnet is initially set in a whirl, swinging on both sides of the position of equilibrium, the real displacement of the equilibrium position being all the same in the direction of the displacement apparent after a few minutes. To prevent confusion, the direction of the displacement apparent after a few minutes has been termed the direction of the first decided movement in Table XXXIX, which contains some data as to the direction given by Ellis and van Bemmelen. The sign means an increase; the sign a decrease of the element.

§ 37. That large magnetic disturbances occur simultaneously over large areas was known in the time of Gauss, whose initiative observations were taken at 5-minute intervals at a number of stations.
on prearranged term days. During March 1879 and August 1880 some large magnetic storms occurred, and the magnetic curves showing these at a number of stations fitted with Kew pattern magnetographs were compared by W. G. Adams. He found the storms so similar as to suggest that they were coincident or simultaneous at all the stations. At comparatively near stations such as Stonyhurst and Kew, or Coimbra and Lisbon, the curves were in general almost duplicates. At Kew and St. Petersburg there were usually considerable differences in detail, and the movements were occasionally in opposite directions. The differences between Toronto, Melbourne or Zia-ke-well and the European stations were still more pronounced. In 1892, on the initiative of M. Eschenhagen, eye observations of declination and horizontal force were made and compared with prearranged Kew patterns at Batavia, Manila, Melbourne and nine European stations. The data from one of these occasions when appreciable disturbance prevailed were published by Eschenhagen, and were subsequently analysed by A. H. Scott. Instead of the usual comparison of the Kew curve with that of any one station, he drew several series of lines, each series representing the disturbing forces at one instant of time as deduced from the departure of the elements at the several stations from their undisturbed value. The angles of deviation to any one instant had a general sense of direction with more or less divergence or convergence, but their general trend varied in a way which suggested to Schmidt the passage of a species of vortex with large but finite velocity.

The analysis of these data tends to show another at nearly equal intervals of time has been reached by several independent observers. J. A. Broun pronounced for a period of about 26 days, and expressed a belief that a certain zone, or area, of the sun's surface might exert a preponderant influence on the earth's magnetism during several solar rotations. Very similar views were advanced in 1904 by E. W. Maunder, who was wholly unaware of Broun's work. Maunder concluded that the period was 10 years, the duration of the sun's relative magnetic life, in terms of 11 years, to an observer on the earth. Taking magnetic storms at Greenwich from 1882 to 1903, he found the interval between the commencement of successive storms to approach closely to the above period in a considerable number of cases. He found further that storms of the same period of time were not the same, and that they were not expected from mere chance. He found several successions of three or four storms, and in one instance of as many as six storms, showing his interval. In a later paper Maunder reached similar results for the period of successions, but he concluded that storms of the same period of time were not the same, and that they were not expected from mere chance. He found several successions of three or four storms, and in one instance of as many as six storms, showing his interval.

A. Schuster examined Maunder's data mathematically, concluded that the period was 10 years, and stated that the formula given by Maunder seems rather strong evidence for having a period of about 10 years. He suggested that the 10-year period was the period of the sun's rotation.

The group of days of largest sun-spot area thus consisted slightly under their share of quiet days and slightly over their share of disturbed days. The differences, however, are not large, and in those cases where the sun-spot area was very large the number of disturbed days actually occurred in group 3, while in 1895, 1896 and 1899 there were fewer quiet days in group 3 than in group 1. Taking the same distribution of days, the mean value of the absolute daily magnetic disturbance was smaller in group 3 than in group 1, and the mean value of the absolute daily magnetic disturbance was smaller in group 3 than in group 1.

The mean range from the group 1 days was the larger in 57% of the individual months as against 43% in which it was the smaller. When the days of each month were divided into groups, the group 3 days of each month were the group with the largest range. At Kew, the mean sun-spot area for the group 1 days (those of largest range) exceeded that for the group 3 days (those of least range) in 55% of the individual months, as against 45% of cases in group 3. Taking next the five days of largest and the five days of least range in each month, sun-spot areas were got out not merely for these days themselves, but also for the next subsequent day and the last day of the preceding day.

Thus, the magnetic theory should we expect the magnetic range to vary with the sun-spot area, not on the actual day but two days previously. The following figures give the percentage excess or deficiency of the mean sun-spot range for the group of days by a, relative to the average value for the whole epoch dealt with. \( n \) denotes the day to which the magnetic range belongs, \( n+1 \) the day after, \( n-1 \) the day before, and

Taking the 11-year means we have the sun-spot area practically normal on the day subsequent to the representative day of large magnetic range, but sensibly above its mean on that day and still more so four days previously. This suggests an emission from the sun taking a highly variable time to travel to the earth. The 11-year mean data for the five days of least range seem at first sight to point to the same conclusion, but the fact that the deficiency in sun-spot area is practically as prominent on the day after the representative day of small magnetic range as on that day itself, or the previous days, shows that the phenomenon is probably a secondary one. On the whole, taking into account the extraordinary difficulty of the results from four previous days, it is within the range of probability that the phenomenon mentioned is caused by a change in the sun itself, or in the wave-length of the sun's rays, as suggested by de Sitter in his observations with the sun's rays.

§ 40. The fact that the moon exerts a small but sensible effect on the earth's magnetism seems to have been first discovered in 1841 by C. Kreil. Subsequently Sabine investigated the nature of the lunar diurnal variation in declination at Kew, Tokyo, Peking, St. Helena, and Hobart. The data in Table XIII are mostly due to Sabine. They represent the mean lunar diurnal inequality in declination for the whole year. The unit employed is 0.001, and as in our case of extreme latitude of the sun's rays, the mean day is the basis of the calculation. The mean departure is the arithmetic mean of the 24-hour departures from the mean value for the lunar day; the range is the difference between the greatest and least. The lunar inequality is also noted for the moon's day, as it is the best idea of the importance of an inequality, especially when in the present case two maxima and minima occur in the day. This double daily period is unusually prominent in the case of the lunar diurnal inequality, and is seen in other elements as well as in the declination.

Lunar action has been specially studied in connection with observations from India and Java. Broun investigated the lunar diurnal inequality at Trivandrum and C. Ebert has recently studied the effects of the sun's rays, and has found a variety of aspects. At Batavia van der Stok and more recently S. Figeé have carried out investigations involving an enormous amount of computation. Table XIII gives a summary of Figeé's results for the mean lunar diurnal inequality at Batavia, for the two half yearly periods April to September (Winter or W.), and October to March (S.). The + sign denotes an increase in the case of declination, but numerical increase in the case of the other elements. The case of H and T (total force) the results for the two seasons present comparatively small differences, but in the case of D, I and V the amplitude and phase both differ widely. Consequently a mean lunar diurnal variation derived from all the months of the year gives at Batavia, and presumably at other

Mean Departure
- Range: 57 35 87 139 144 214 155 81 184 156

The most notable recent example of observations at sea is afforded by the cruises of the survey ships H. L. H. Expedition and the Empresa. These ships have been fitted with total force observation equipment, and are able to carry out operations in the open ocean without the hindrance of land or coast. In the case of the Empresa, the total force observations were taken in the South Atlantic, and the results are being published in a series of papers in the Philosophical Transactions of the Royal Society of London.

The situation whether lunar influence increases with sun-spot frequency is obviously of considerable theoretical interest. Ball and Stewart in the 9th edition of their Encyclopaedia gave some data indicating an appreciably enhanced lunar influence at Trivandrum during years of sun-spot maximum, but he hesitated to accept the result as finally proved. Fige has recently investigated this point at Batavia, and with inconclusive results. Attempts have also been made to ascertain how lunar influence depends on the moon's declination and phase, and on her distance from the earth. The difficulty in these investigations is that Batavia is on the coast of the Indian Ocean, and the corresponding ranges in H are only 13°, 18°, and 25° respectively.

exactitude with which the sites can be recovered, on the accuracy of the observations, and on the success with which allowance is made for diurnal changes, regular and irregular. It is thus desirable that the observations at repeat stations should be taken at hours when the regular diurnal changes are most likely to be accepted unless taken on days that prove to be magnetically quiet. Unless the secular change is exceptionally rapid, it will usually be most convenient in practice to calculate it from or to the middle of the month (for the forward formulae) or from the first day of the month (for the backward formulae) to the time of the observation, and to apply the value for the month and the value at the actual hour of observation. There is here a difficulty, inasmuch as the latter part of the correction depends on the diurnal inequality, and so on the local time of the station. But since a great deal of confidence has been placed in that difficulty has yet been proposed. Rücker and Thörpe in their British survey assumed that the divergence from the mean value at any hour at any station might be regarded as made up of a regular diurnal change combined with a similar change, referred to local time, and of a disturbance element identical with that existing at the same absolute time at Kew. Suppose, for instance, that at hour $h$ G.M.T. the departure at Kew from the mean value for the month is $d$, then the corresponding departure from the mean at a station $\lambda$ degrees west of Kew is $d-e$, where $e$ is the increase in the element at Kew due to the regular diurnal inequality at hour $h-\lambda/15$ and hour $h$. This procedure is simple, but it is exposed to various criticisms. If we define a diurnal inequality as the result obtained by combining hourly readings from all the days of a month, we can assign a definite meaning to the diurnal inequality for a particular month of a particular year, and after the curves have been drawn for a number of years, given data, and improve to this definition. But the diurnal inequality thus obtained differs, as has been pointed out, from that derived from a limited number of the days of the month, not merely in amplitude but also in phase, and it is, therefore, characterized by considerable uncertainty. It is regarded as made up of a regular diurnal inequality of definite character and of a disturbance element is an hypothesis which is likely at times to be considerably wide of the mark. The extent of the error involved in assuming a diurnal inequality to exist, if such is the case, is easily estimated from the formulae of the theory and the curves derived from them. It is, however, a considerable simplification, and a dangerous one, to ignore the effects of the disturbance element.

§ 43. The field results having been reduced to a fixed epoch, it remains to combine them in ways likely to be useful. In most cases the results are embodied in charts, usually of at least two kinds, one short-based and the other long-based, which are expressly recommended for this purpose. Charts of the first kind resemble the world charts (figs. 1 to 4) in being free from sharp twistings and convolutions. In these the declination for instance at a fixed geographical position on a particular date is regarded as really a mean from a considerable surrounding area.

Various ways have been utilized for arriving at these terrestrial isomagnetic lines. The simplest method is to employ Lázár for Austria-Hungary. Let $l$ and $\lambda$ represent latitude and longitude respectively, and let $T$ be the time at a particular central station in the area. Then assume that throughout the area the value $E$ of any particular magnetic element is given by a formula

$$E = E_0 + \alpha l + \beta \lambda + \gamma t + \eta + \delta l + \xi \lambda,$$

where $E_0$, $\alpha$, $\beta$, $\gamma$, $\eta$, $\delta$, $\xi$ are absolute constants to be determined from the observations. When determining the constants, we write for $E$ in the equation the observed value of the element (corrected for secular change, &c.) at each station, and for $l$ and $\lambda$ the latitude and longitude of the observation, and for $t$ the time, the observation being regarded as contributing an equation to assist in determining the six constants. They can thus be found by least squares or some simpler method. In Lázár's case there were 195 stations, so that the labour of calculation would have been very considerable. It was accordingly found advisable to employ a method of iteration to the method. A second is that it may allow undeniably large weight to a few highly disturbed stations. In the case of the British Isles, Rücker and Thörpe employed a different method. The area was divided into number of districts, and for each of these the observed values of each element, and the mean was assigned to an imaginary central station, whose geographical co-ordinates represented the mean of the geographical co-ordinates of the actual stations. For the disturbance element, values may be allowed for by weighting the results. Supposing $E_0$ the value of the element found for the central station of a district, it was assumed that the value $E$ at any actual station whose latitude and longitude exceeded those of the central station by $l$ and $\lambda$ was given by $E = E_0 + \alpha l + \beta \lambda$, with $a$ and $b$ constants throughout the district. Having found $E_0$, $a$, and $b$, Rücker and Thörpe calculated values of the element for points defined by whole degrees of longitude (from Greenwich) and half degrees of latitude. Near the common border of two districts there would be two calculated values, of which the least was selected as representing the true value.

The next step was to determine by interpolation where isogons —or other isomagnetic lines—cut successive lines of latitude. The curves formed by joining these successive points of intersection were then constructed, and the position of the isomagnetic lines obtained by trial, giving smooth curves of continuous curvature—terrestrial isomagnetic—approximating as closely as possible to the district lines. The curves thus obtained had somewhat the character of the lines of longitude. The declination formula thus obtained for the epoch Jan. 1, 1891, was

$$D = 18° 37' + t\times18° 35' + 0.0010\cos(\lambda - 45° - 5^\circ) + 0.00005\cos(\lambda - 45° - 5^\circ)^2 + 0.00005\sin(\lambda - 45° - 5^\circ)^2,$$

where $1° + 5(30° 30')$ represents the latitude, and $(\lambda - 5° 35')$ the longitude of the station. From this and the corresponding formulae for the other elements, values were calculated for each of the district stations, and from these the isomagnetic lines were determined. A complete record is given of the differences between the observed and calculated values, and of the corresponding differences obtained by Rücker and Thörpe from their own formulae. Where the differences were very considerable, the two methods are almost exactly the same—being approximately 10 or less for declination, 54° or inclination, and 70° for horizontal force. The applications by Mathias and B. Balland have applied to Rücker and Thörpe's, and the magnetic data found for the nine imaginary central stations, they employed these to determine the six constants of the isomagnetic formulae. The method dispenses entirely with district curves, and the parabolic formulae are perfectly straightforward both to calculate and to apply; they thus appear to possess marked advantages. Whether the method could be applied equally satisfactorily to an area of the size of India or the United States actual trial alone would show.

§ 44. Rücker and Thörpe regarded their terrestrial isomagnetic and isomagnetic lines as definitive, and thought that they would exist in the absence of disturbances peculiar to the neighbourhood. Subtracting the forces derived from the formulae from those observed, we obtain forces which could be ascribed to local disturbances.

When the vertical disturbing force is downwards, or the observed vertical component larger than the calculated, Rücker and Thörpe regard it as positive, and the loci where the largest positive values occur they termed $ridge$ lines. The corresponding loci where the largest negative values occur were called $valley$ lines. In the British Isles Rücker and Thörpe found that almost without exception, in the neighbourhood of a ridge line, the horizontal component of the disturbance takes a minimum, and points towards it, throughout a considerable area on both sides. The phenomena are similar to what would occur if ridge lines indicated the position of the summits of underground masses of magnetic material, magnetized so as to attract the magnetic needle. In their seeking for the source of such lines, Rücker and Thörpe were inclined to believe in the real existence of these subterranean magnetic mountains, and inferred that they must be of considerable extent, as theory and observation alike indicate that thin basaltic layers, or caverns, or even meta-sedimentary beds of magnetic material, are the only means of producing measurable magnetic effect except in their immediate vicinity. In support of their conclusions, Rücker and Thörpe dwell on the fact that in the United Kingdom large masses of basalt such as occur in Skye, Mull, and the Scilly Isles, would have been discovered according to their survey invariably centres of attraction for the north-seeking pole of a magnet. Various cases of repulsion have, however, been described by other observers in the northern hemisphere.
MAGNETISM, TERRITORIAL

(48° N. lat., 35° E. long.) was elaborately surveyed by Paul Passalski. The extreme values observed by him differed, the declination by 28° 40', the inclination by 41° 53', horizontal force by 0-658, and vertical force by 1-358. At one spot a difference of 110° 3 was observed between declinations at stations only 45 metres apart. Though the shallow vertical disturbances of a not very inferior order of magnitude have been met with. Possibly the most outstanding case known is that of an area, about 3 m. long by 12 m. at its widest, near Port Walcott, off the coast of Western Australia. The variations here by H.M.S. "Penguin" have been discussed by Captain E. W. Creagh. Within the narrow area specified, declination varied from 26° W. to 56° E., and inclination from 50° to nearly 80°, the observations being made by J. L. Adams. An interesting case, though hardly comparable with the above, is that of East Lothian at Lewis in the Hebrides. A survey by H.M.S. "Research" in water about 100 ft. deep—discussed by Admiral A. F. M. infants and the other authors—showed that the largest observed disturbances in horizontal and vertical force were of the order 0-02 and 0-05 C.G.S., respectively. An interesting feature in this case was that vertical force was reduced, there being a well-marked valley line.

In recent instances, regional magnetic disturbances have been found to be associated with geoelectrical anomalies. This is true of an elongated area including Moscow, where observations were taken by Fritsche. Again, Eschenhagen detected magnetic anomalies in an area 5 km. square near Moscow, where strong deflections of the plumb line from the normal had been observed. He found a magnetic ridge line running approximately parallel to the line of no deflection of the plumb line.

§ 47. The greatest interest, about which however not very much is known, is the effect of local disturbance on secular change and on the diurnal inequality. The determination of secular change in a highly disturbed locality is difficult, because an unintentional slight change in the position of the observatory would wholly falsify the conclusions drawn. When the disturbed area is very limited in extent, the magnetic field may reasonably be regarded as composed of the normal field that would have existed in the absence of the disturbances, increased by a sum of vectorial quantities from magnetic material which approaches nearly if not quite to the surface. Even if no sensible change takes place in the disturbance field, one would hardly expect the secular change to be normal. The changes in the rectangular components of the force may possibly be the same as at a neighbouring undisturbed station, but this will not give the same change in declination and inclination. In the case of the diurnal inequality, the presumption is that at least the declination and inclination changes will be influenced by local disturbance. If, for example, we suppose the horizontal force to be disturbed by a sum of vectorial forces arising from electric currents in the upper atmosphere, the declination change will represent the action of the component of a force of given magnitude which is perpendicular to the line of force. But while local disturbances do exist, the direction of the needle and the intensity of the controlling field are both altered by the local disturbance, so it would appear natural for the declination changes to be influenced accordingly. The other pattern integral powers of the radius made by Passalski and Krivoi Rog, which showed diurnal inequalities differing notably from those experienced at the same time at Odessa, the nearest magnetic observatory. One station where the horizontal force was abnormally reduced was taken by A. F. M. infants, and the other by zero. It was impossible to avoid local loss when selecting a site for a magnetic observatory, assuming one's object is to obtain data reasonably applicable to a large area. In the case of the older observatories this consideration seems sometimes to have been a serious disadvantage, because, instead of a circle of only 56 ft. radius, having for centre the declination pillar of the Royal Alfred Observatory, T. F. Claxton found that the declination varied from 4° 50' to 13° 45' W., the inclination varied from 32° to 68° W., the earth's magnetic constant was found to be 0-107 to 0-244 C.G.S. At one spot he found an alteration of 1° 3 in the declination when the magnet was lowered from 4 ft. above the ground to 2. Disturbances of this order could hardly escape even a rough observer.

If we assume the magnetic force on the earth's surface derivable from a potential V, we can express V as the sum of two series of solid spherical harmonics, one containing a constant term, and the other containing a vector $r$ from the earth's centre. Let $\lambda$ denote east longitude, $\phi$ north latitude, and $\mu = \cos(\lambda - \ell)$, where $\ell$ is longitude; and also let

$$H_n = (1+i^2)n[H_n^((\mu^2)) \cos m \lambda + H_n^((\mu^2)) \sin m \lambda)]$$

where $n$ and $m$ denote any positive integers, $\mu$ being not greater than $n$. Then denoting the earth's radius by $R$, we have

$$V = \sum (R/r)^n (H_n^((\mu^2)) \cos m \lambda + H_n^((\mu^2)) \sin m \lambda)$$

where $\sum$ denotes summation of $m$ from 0 to $n$, followed by summation of $n$ from 0 to $\infty$. In this equation $H_n^((\mu^2))$ are constants, those with positive suffixes being what are generally termed Gaussian constants. The series with negative powers of $r$ answers to forces with a source internal to the earth, the series with positive powers to forces with an external source. Gauss found that forces of the latter kind were very small, and they are usually left out of account. There are three Gaussian constants of the first order, $g_0$, $g_1$, $h_0$, five of the second order, seven of the third, and so on. The coefficient of a Gaussian constant of the $n$th order is a spurious harmonic of the $n$th degree. If $R$ be taken as unit length, as is not infrequent, the first order terms are given by

$$V_1 = g_0 \sin \lambda + g_1 \cos \lambda \sin \lambda \cos \phi$$

Supposing the Gaussian constants known, the above formulae would express the force over the earth's surface. To determine the Gaussian constants we proceed of course in the reverse direction, equating the observed values of the force components to the theoretical values involving $g_0$ and $g_1$. If we knew the values of the component forces at regularly distributed stations all over the earth's surface, we could determine each Gaussian constant independently of the others. Our knowledge however of large regions, especially in the Arctic and Antarctic, is very scanty, and in practice recourse is had to methods in which the constants are not determined independently. The values held for Gaussian constants have sometimes found support in the case, even amongst the lower orders, depend very sensibly on how large a portion of the polar regions is omitted from the calculation.

Calculations, and on the other hand the number of the constants of the higher orders are retained.

Table XIV. gives the values obtained for the Gaussian constants of the first order in some of the best-known computations, as collected by W. G. Adams. Allowance must be made for the difference in the epochs, and for the fact that the number of constants assumed to be worth retaining was different in each case. Gauss, for instance, assumed 24 constants sufficient, whilst in obtaining the results given in the table J. C. Adams retained 48. Some idea of the uncertainty thus arising may be derived from the fact that when Adams assumed 24 constants sufficient, he got instead of the values in the table the following:

| 1842-1845 | +032173 | +02533 | -00820 |
| 1880 | +02360 | +02470 | +00607 |

Some of the higher constants were relatively much more affected. Thus, on the hypotheses of 48 and of 24 constants respectively, the value obtained for $g_0$ in 1845 was +00748 and +00573. It must also be remembered that these values assume that the series in positive powers of $r$, with coefficients having negative suffixes, is absolutely correct. For the first 100 terms the error is negligible, but for the higher terms it may become considerable. In any equation determining $Z$ by $g_0 = [n(t+1)] Z$; similar remarks apply to $h_0$ and $h_0$. It is thus theoretically possible to check the truth of the assumption that the positive power series is non-existent by comparing the values obtained for $g_0$ and $h_0$ from the $X$ and $Y$ or from the $Z$ equations, when $g_0$ and $h_0$ are assumed zero. If the values so found differ, values can be found for $g_0$ and $h_0$, which will harmonize the two sets of equations. Adams gives the values obtained from the $X$, $Y$ and $Z$ equations separately for the
Gaussian constants. The following are the examples of values thence deducible for the coefficients of the positive power series:

\[
\begin{array}{cccc}
\text{Epoch} & \text{Authority for Constants} & \text{North Latitude} & \text{West Longitude} & \text{M/R}^2 \text{in G.C.S. units} \\
1842-1845 & H. Fritsche & +0.018 & -0.002 & +0.014 & +0.004 & +0.012 & +0.014 \\
1880 & -0.002 & +0.015 & -0.003 & -0.013 & \\
\end{array}
\]

Compared to \(g_1^2\), \(g_2^4\) and \(g_3^6\) the values here found for \(g_4^1\), \(g_5^3\) and \(g_6^5\) are far from insignificant, and there would be no excuse for neglecting them if the observed values were sufficiently reliable. But two outstanding features claim attention, first the smallness of \(g_1^2\), \(g_2^4\) and \(h_1^1\), the coefficients least likely to be affected by observational deficiencies, and secondly the striking dissimilarity between the values obtained for the two epochs. The conclusion to which these and other facts point is that observational deficiencies, even up to the present date, are such that no certain conclusion can be drawn as to the existence or non-existence of the positive power series. It is perhaps tolerable to say that considerable uncertainties are inherent in the values of most of the Gaussian constants, at least those of the higher orders. The introduction of the positive power series necessarily improves the agreement between observed and calculated values of the force, but it is more likely than not to be disadvantageous physically, if the differences between observed values and those calculated from the negative power series alone arise in large measure from observational deficiencies.

§ 49. The first order Gaussian constants have a simple physical meaning. The terms containing them represent the potential axis, and the coefficients between them and a fixed axis; the moment of the spherical magnet being given by

\[ M = R^3 (g_1^2) \]

where \( R \) is the earth's radius. The position of the north end of the axis of this uniform magnetization and the values of \( M/R \), derived on the assumption that the earth's pole is the north end of the axis, are given in Table XLV. The data for 1860 are of some what doubtful value; if they were as reliable as the others, one would feel greater confidence in the reality of the apparent movement of the north end of the axis from east to west. The table also suggests a slight diminution in \( M \) since 1845, but it is open to doubt whether the apparent change exceeds the probable error in the calculated values. It should be carefully noticed that the data in the table are applicable only to the first order Gaussian terms, and so only to a portion of the earth's magnetic field. The coefficients of higher order constants have been calculated on the assumption that the negative power series alone exists. The field answering to the first order terms is what Bauer has called the normal field; constitute much the most important part of the whole magnetization. Still, what remains is very far from negligible, save for rough calculations. It is in fact one of the weak points in the Gaussian analysis that when one wishes to represent the observed facts with high accuracy one is obliged to retain so many terms that calculation becomes burdensome.

§ 50. The possible existence of a positive power series is not the only theoretical uncertainty in the Gaussian analysis. There is the further possibility that the part of the earth's magnetic field may not answer to a potential at all. Schmidt in his calculation of Gaussian constants regarded this as a possible contingency, and the results he reached implied that as an average current over the whole earth's magnetic field, has been clock-wise or anti-clockwise. In applications of the formula by W. von Bezold and Bauer the integral has been taken along parallels of latitude in the direction west to east. In this case a + sign indicates a result from a current flowing out over the area of latitude traversed and the north geographical pole. The difference between the results of integration round two parallels of latitude gives the total vertical current over the zone between them. Schmidt's final estimate of the average intensity of the earth-air current, irrespective of sign, for the epoch 1885 was 0.17 ampere per square kilometre. Bauer employing the same observational data as Schmidt, reached somewhat similar conclusions from the differences between integrals taken round parallel of latitude at 5° intervals from 60° N. to 60° S. H. Fritsche treating the problem for the year 1885, got cosiderably different results for the two epochs, Bauer has more recently repeated his calculations, and for three epochs, 1842-1845 (Sabine's charts), 1880 (Creek's charts), and 1885 (Neumayer's charts), obtaining the mean values of the deflection of the needle for 5° true north, and for 5° zones. Table XLVI. is based on Bauer's figures, the unit being e°001 ampere, and also denoting an upwardly directed current.

In considering the significance of the data in Table XLVI., it should be remembered that the currents must be regarded as mean values derived from all hours of the day, and all months of the year. Currents which were upwards during certain hours of the day, and downwards during other hours, or vice versa, would cause a difference in average intensity. While currents which were upwards during certain months, and downwards during others, would cause an annual inequality in the absolute values. Thus, if the figures be accepted as real, we must suppose that on 15° N. and 45° S. 0° and 15° S. preponderating upward currents. Such currents might arise from meteorological conditions characteristic of particular latitudes, or be due to the relative distribution of electric currents in the atmosphere. In any case, the real changes are indefinite in their values between 1842 and 1885 seems very improbable. The most natural cause to which to attribute the difference between the results for different epochs in Table XLVI. is unquestionably observational deficiency, but whatever their cause, any considerable real change in their values between 1842 and 1885 seems very improbable. In calculating the effect of these on the observational charts, seem difficult to reconcile with the results of atmospheric electricity (q.e.).

§ 51. There is no single parallel of latitude along the whole of which magnetic elements are known with high precision. Thus, results of greater certainty might be hoped for from the application of the line integral to well surveyed country. Such applications have been made, e.g. to Great Britain by Rücker, and to Austria by Liznar. The results of these calculations have been considered in detail by Tanaka in discussing the magnetic survey of Japan. He makes the criticism that the taking of a line integral round the boundary of a surveyed area amounts to utilizing magnetic elements of which, at least approximately, he knows the value. But, whatever his cause, any considerable real changes in their values between 1842 and 1885 seems very improbable. He applied this formula not merely to his own data for Japan, but also to British and Austrian data of Rücker and Thorpe and of Liznar. The values he ascribes to X and Y are those given by the corresponding coefficients of the observations. The result reached was "a line of no current through the middle of the country in Japan the current is upward on the Pacific side and downward on the Siberian side; in Austria it is upward in the north and downward in the south. In Great Britain the magnetic field is upward in the middle of the country." The results obtained for Great Britain differed considerably as use was made of Rücker and Thorpe's own magnetic models of the type subsequently calculated by Tanaka in discussing the magnetic survey of Japan. He makes the criticism that the taking of a line integral round the boundary of a surveyed area amounts to utilizing magnetic elements of which, at least approximately, he knows the value. But, whatever his cause, any considerable real changes in their values between 1842 and 1885 seems very improbable. A question of interest, and bearing a relationship to the Gaussian analysis, is the law of variation of the magnetic elements with height above sea-level. If \( F \) represent the value at sea-level, and \( F' \) that at \( h \) above sea level, then the value of the Gaussian constants of the \( (h) \) order, that is \( 1+e^F/1+e^{-F} \), is taken at the altitude \( h \) above sea level. Thus at heights of only a few miles we have very approximately \( F' = F + e^{-F} \). As we have seen, the constants of the first order are the most important, thus we should expect as a first approximation \( F' = F - 2h \). This equation gives the same rate of decrease in all three components, and no change in declination or inclination. In order to compare this equation with the observed results of his Austrian survey, subdividing his results into three groups according
MAGNETISM, TERRESTRIAL

to altitude. He considered the agreement not satisfactory. It must be remembered that the Gaussian analysis, especially when only lower order terms are retained, applies only to the earth's field freed from local disturbances. Now observations at individual high and low points in mountains will depict disturbances to low level stations, but by magnetic material in the mountain itself. A method of arriving at the vertical change in the elements, which theoretically seems less open to criticism, has been employed at Rome, and this will be described in the next chapter, admitting the possibility of earth-air currents we assume their effort negligible, we have \( \Delta H = \Delta H' \) = \( \Delta H'' \), \( \Delta D = \Delta D' \) = \( \Delta D'' \), where \( \Delta H \), \( \Delta D \) is the difference of the magnetic field.

The observed rates of change of the vertical component of force do not at all agree with the simple least squares for the case of change in the vertical direction of the two rectangular components of horizontal force, and hence the values of change of the horizontal force and the declination. Also we have \( \Delta H = \Delta H' \) = \( \Delta H'' \), \( \Delta D = \Delta D' \) = \( \Delta D'' \), where \( \Delta H \), \( \Delta D \) is the difference of the magnetic field.

The \( \Delta D \) is based on the magnetic field. The data were used as defined in § 5. In the case of H and V unity represents 1.5.

### Schuster's General Variation Potential.

From the mean summer and winter diurnal variations of the northerly and easterly components of force during the month of August at Lister and Mayen and South Victoria Land in Tables VIII. to XI. The case, however, of declination allowance must be made for the small size of \( H \). If a force \( F \) perpendicular to the magnetic meridian direction change \( \Delta D \) then \( \Delta D = H/H. \) Thus at the Discovery's winter quarters in South Victoria Land, where the value of \( H \) is only about 0.36 of that at Kew, a change of 45° in \( D \) will be produced by a force which at Kew would produce a change of 45° in \( H \). Another feature, which, however, may not be equally general, is illustrated by the data for Fort Rae and South Victoria Land in Table XVII. It will be noticed that it is the 24-hour term in the Fourier analysis which is enhanced. The station in South Victoria Land—the winter quarters of the "Discovery" in 1902-1904—was at 77° 51' S. lat.; thus the sun did not set from November to February (midsummer), nor rise from May to July (midwinter). It might not therefore be considered surprising that the midsummer months show a very marked inequality in the type of the diurnal inequality. As a matter of fact, however, the type of the inequality showed exceptionally small variation with the season, and the amplitude remained large through all the direct opposition of the solstices. The greatest change from the midsummer months and for the three midwinter months, we obtain the following amplitudes for the range of the several elements

- D: H. V. Midsummer 6° 11' 57' 18° 2° 57'
- Midwinter 26° 8° 257° 18° 1° 23'

The most outstanding phenomenon in high latitudes is the frequency and large size of the disturbances. At Kew, as we saw in § 25, the absolute range in D exceeds 20° only 12% of the total number of days. It was about 2° in the sun-spot minimum, the range exceeded 1° on 70% of days, and on 3° on 15% of the total number of days. One case in 25 had a range exceeding 4°. During the three midsummer months, only one day in 111 had a range exceeding 4°, whereas in the three midwinter months, only one day in eight had a range as small as 30°. The H range at the "Discovery's" station exceeded 100° on 40% of the days, and the V range exceeded 100° on 32% of the days.

The solar tides are most marked in equinoctial months at moderate latitudes. The equinoctial months did not appear in the "Discovery's" records in the Antarctic. D ranges exceeded 3° occurred on 11% of equinoctial days, but on 40% of midsummer days. The preponderance of large movements at 90° south was thus due to the sun, and the other elements were in line with the sun. The percentage of days having a V range over 200° was 21 at midsummer, as against 3 in the four equinoctial months.

At the "Discovery's" station small oscillations of a few minutes' duration were hardly ever absent, but the character of the larger disturbances showed a marked variation throughout the 24 hours.
MAGNETISM, TERRESTRIAL

Those of a very rapid oscillatory character were especially numerous in the morning between 4 and 9 a.m. In the late afternoon and evening disturbances of a more regular type became prominent, especially in the winter months. In particular there were numerous occurrences of such type which regularly recur in the middle of all the total number of cases taking place between 7 and 9 p.m. This "special type of disturbance" was divisible into two phases, each lasting on the average about 20 minutes. During the first phase all the elements directed from the south to the north, and the second from the north to the south. Similar type of disturbance was observed by K. Birkeland in the North Pole, and by C. Chree on the other hand, working up the 1902-1903 Antarctic records, discovered that, during the larger disturbances of the "special type" corresponding but much more noticeably, the observation of South Pole stations was shifted to the east, and those of the Arctic, to the west. The change in order of magnitude, though apparently of considerably different type.

Examining the more prominent of the sudden commencements of magnetic disturbances in 1902-1903 visible simultaneously in the entire northern and southern hemispheres, Moore also found that these were all represented in the Antarctic curves by movements of a considerably larger size and of an oscillatory character. In a number of cases Birkeland observed small simultaneous movements in the curves of his cooperating stations, which appeared to be at least sometimes considerably larger in the equatorial than in the northern temperate stations. He described as "equatorial" perturbations, ascribing them to electric currents in or near the plane of the earth, which could be produced by the electric currents in the sun and the electric currents in the earth or the moon.

Magnetic Poles.

Antarctic observations made by the "Erebus" and "Terret," expedition is shown in Sabine's chart as about 73° 30' S. 147° 30' W., on recent chart in J. C. Adams's Collected Papers, vol. 2, the position of both being about 73° 30' S. 147° 30' W. Of late years positions have been obtained for the south magnetic pole by the "Southern Cross" expedition of 1898-1900 (A), by the Discovery in 1902-1904 (B), and by Sir E. Shackleton's expedition of 1907-1909 (C). Their positions are:

(A) 72° 40' S. 152° 30' E.
(B) 72° 51' S. 156° 25' E.
(C) 72° 25' S. 155° 16' E.

Unless the diurnal inequality vanishes in its neighbourhood, a somewhat improbable and rare occurrence, it may be said that "Discovery's" winter quarters, the position of the south magnetic pole has probably a diurnal oscillation, with an average amplitude of several miles, and there is not unlikely a larger annual oscillation. Thus the position of the magnetic pole of the earth can probably claim to be a magnetic pole in the sense popularly ascribed to the term. If the diurnal motion were absolutely regular, and carried the point where the needle is vertical round a closed curve, the centroid of that curve—though a spot the needle is never absolutely vertical—would seem to have the best claim to the title. It should also be remembered that when the dip is nearly 0° there are special observational difficulties. There are thus various reasons for allowing a considerable uncertainty in positions assigned to the magnetic poles. Conclusions as to change of position of the magnetic pole during the last ten years is based on the more recent results (A), (B), and (C) would, for instance, possess a very doubtful value. The difference, however, between these recent positions and that deduced from the observations of 1840-1841 is such that a moderate probability that a considerable movement towards the north-east has taken place during the last seventy years.

See publications of individual magnetic observers, more especially the Russian (Annales de l'Observatoire Physique Central), and Birkeland's "Magnetismus," for which see also "The Earth's Magnetic Field" and those of Kew, Greenwich, Falmouth, Stonyhurst, Fotsdam, Wilhelmshaven, de Bilt, Uccle, O'Gyalla, Prague, Pola, Coimbra, San Fernando, Capo di Monte, Tiflis, Kolasha, Z-fa-wei, Hong-Kong, and the observatories of the U.S. Coast and Geodetic Survey, Rio de Janeiro, Melbourne.

The terms "Magnetismus" and "Magnetometers" are used to designate terrestrial and auroral magnetic fields, respectively, and the latter term is reserved for the phenomena relating to the latter portion of the spectrum.

MAGNETITE.—MAGNETOGRAPH

MAGNETITE, a mineral forming the natural magnet (see MAGNETISM), and important also as an iron-ore. It is an iron-black, opaque mineral, with metallic lustre; hardness about 6, sp. gr. 4-9 to 5-2. When scratched, it yields a black streak. It is an oxide of iron having the formula Fe$_3$O$_4$, corresponding with 72.4% of metal, whence its great value as an ore. It may be regarded as a ferro-ferric oxide, FeO.Fe$_2$O$_3$, or as iron ferrate, Fe$_5$FeO$_4$. Titanium is often present, and occasionally the mineral contains magnesium, nickel, &c. It is always strongly magnetic. Magnetite crystallizes in the cubic system, usually in octahedra, less commonly in rhombic dodecahedra, and not infrequently in twins of the "spinel type" (fig. 1). The rhombic faces of the dodecahedron are often striated parallel to the longer diagonal. There is no distinct cleavage, but imperfect parting may be obtained along octahedral planes.

Magnetite is a mineral of wide distribution, occurring as grains in many massive and volcanic rocks, like granite, diorite and dolerite. It appears to have crystallized from the magma at a very early period of consolidation. Its presence contributes to the dark colour of many basaltic and andesitic rocks, and may cause them to disturb the compass. Large ore-bodies of granular and compact magnetite occur as beds and lenticular masses in Archean gneiss and crystalline schists, in various parts of Norway, Sweden, Finland and the Urals; as also in the states of New York, New Jersey, Pennsylvania and Michigan, as well as in Canada. In some cases it appears to have segregated from a basic eruptive magma, and in other cases to have resulted from metamorphic action. Certain deposits appear to have been formed, directly or indirectly, by wet processes. Iron rust sometimes contains magnetite. An interesting deposit of oolithic magnetic ore occurs in the Dogger (Inferior Oolite) of Rosedale Abbey, in Yorkshire; and a somewhat similar pisolithic ore, of Jurassic age, is known on the continent as chamosite, having been named from Chamoson (or Chamson) in the Valais, Switzerland. Grains of magnetite occur in serpentine, as an alteration product of the olivine. In emery, magnetite in a granular form is largely associated with the corundum; and in certain kinds of mica magnetite occurs as thin dendritic enclosures. Haematite is sometimes magnetic, and A. Liversidge has shown that magnetite is probably present. By dehydration, haematite may be converted into magnetite, as proved by certain pseudomorphs; but on the other hand magnetite is sometimes altered to haematite. On weathering, magnetite commonly passes into limonite, the ferrous oxide having probably been removed by carbonated waters. Closely related to magnetite is the rare volcanic mineral from Vesuvius, called magnoferrite, or magnesioferrite, with the formula MgFe$_2$O$_4$; and with this may be mentioned a mineral from Jakobsberg, in Vemland, Sweden, called jakobsite, containing MnFe$_2$O$_4$.

MAGNETOGRAPH, an instrument for continuously recording the values of the magnetic elements, the three universally chosen being the declination, the horizontal component and the vertical component (see TERRESTRIAL MAGNETISM). In each case the magnetograph only records the variation of the element, the absolute values being determined by making observations in the neighbourhood with the unifilar magnetometer (q.v.) and inclinometer (q.v.).

**Declination.**—The changes in declination are obtained by means of a magnet which is suspended by a long fibre and carries a mirror, immediately below which a fixed mirror is attached to the base of the instrument. Both mirrors are usually concave; if plane, a concave lens is placed immediately before them. Light passing through a large collimating slit is reflected by the moving mirror to the fixed mirror, and two images of the slit are produced, one by the movable mirror attached to the magnet and the other by the fixed mirror. These images would be short lines of light; but a plano-cylindrical lens is placed axial to the axis of the magnetic needle, which is fixed. In this way a spot of light is obtained from each mirror. The recording surface is a sheet of photographic paper wrapped round a drum which is rotated at a constant speed by clockwork about a horizontal axis, and light reflected on the drum from the mirror attached to the fixed axis of the magnetic needle is recorded on the paper, serving as a base line from which the variations in declination are measured. As the declination changes the spot of light reflected from the magnet mirror moves parallel to the axis of the recording drum, and the drum and the mirror attached to this spot by this base line gives, for any instant, on an arbitrary scale the difference between the declination and a constant angle, namely, the declination corresponding to the base line. The value of this constant angle is obtained by comparing the record with the value for the declination as measured with a magnetometer. The value in terms of arc of the scale of the record can be obtained by measuring the distance between the magnet mirror and the recording drum. In most observations it is such that a millimetre on the record represents one minute of arc. The spot on the recording drum employed is 15 mm. per hour, but in modern instruments provision is generally made for the time scale to be increased at will to 160 mm. per hour, so that the more rapid variations of the declination can be followed. The advantages of using small spots of light are that the moment of inertia may be small and hence they may be able to respond to rapid changes in the earth’s field, were first insisted upon by E. Mascart, while M. Eschenhagen first designed a set of magnets in which the declination was recorded on the drum by a spot of light. Further, as the light was taken to the recording drum, it was unnecessary to expose the ground glass plate to the light when the magnetic needle was carried to its useful limit, the magnets only weighing 15 g gram each, and the suspension consisting of a very fine quartz fibre.

**Horizontal Force.**—The variation of the horizontal force is obtained by the rotation of a magnet which is carried by a fine fibre or by a fairly stiff metal wire or quartz fibre. The upper end of the suspension is turned till the axis of the magnet is at right angles to the magnetic meridian. In this position the magnet is held in a horizontal drum and a magnetic needle is attached to the upper end of the bifilar suspension, so arranged that with rise of temperature the fibres are brought nearer together and hence the value of $\theta$ decreases. Since such a decrease in $\theta$ would by itself give a fictitious increase of the magnet to turn in the same direction as if $H$ had increased, it is possible in a great measure to neutralize the effects of temperature on the reading of the instrument. In the case of the unifilar suspension, the provision of a temperature compensation is not so easy, so that what is generally done is to provide the instrument with a temperature compensation so that the reading imparted to the suspension, two magnets are placed in the vicinity of the suspended magnet and are so arranged that their field partly neutralizes the earth’s field; thus the torsion required to hold the magnet with its axis horizontal results in a change which neither the magnet nor the suspension permits of the sensitiveness being altered by changing the position of the deflecting magnets. Further, by suitably choosing the positions of the deflectors and the coefficient of torsion of the suspension it is possible to devise a compensation (for instance) (See Adolf Schmidt, Zeits. für Instrumentenkunde, 1907, 27, 145.)

The method of recording the variations in $H$ is exactly the same as that adopted in the case of the declination, and the sensitiveness generally adopted is such that a variation of 1 degree in $H$ of 0-0005 C.G.S., the time scale being the same as that employed in the case of the declination.

**Vertical Component.**—To record the variations of the vertical component, and to avoid the difficulty between horizontal and vertical, so that it can be freely about a horizontal axis at right angles to its...
MAGNETOMETER

The elements which are actually measured when determining the value of the earth's field are usually the declination, the dip and the horizontal component (see MAGNETISM, TERRESTRIAL). For the instruments and methods used in measuring the dip see INCLINOMETER. It remains to consider the measurement of the declination and the horizontal component, these two elements being generally measured with the same instrument, which is called a unifilar magnetometer.

Measurement of Declination.—The measurement of the declination involves two separate observations, namely, the determination of (a) the magnetic meridian and (b) the geographical meridian, the angle between the two being the declination. In order to determine the magnetic meridian the orientation of the magnetic axis of a freely suspended magnet is observed; while, in the absence of a distant mark of which the azimuth is known, the geographical meridian is obtained from observations of the transit of the sun or a star. The geometrical axis of a magnet is sometimes defined by means of a mirror rigidly attached to the magnet and having the normal to the mirror as nearly as may be parallel to the magnetic axis. This arrangement is not very convenient, as it is difficult to protect the mirror from accidental displacement, so that the angle between the geometrical and magnetic axes may vary. For this reason the end of the magnet is sometimes polished and acts as the mirror, in which case no displacement of the reflecting surface with reference to the magnet is possible. A different arrangement, used in the instrument described below, consists in having the magnet hollow, with a small scale engraved on glass firmly attached at one end, while to the other end is attached a lens, so chosen that the scale is at its principal focus. In this case the geometrical axis is the line joining the central division of the scale to the optical centre of the lens. The position of the scale is observed by means of a small telescope, and since the scale is at the principal focus of the lens, the scale will be in focus when the telescope is adjusted to observe a distant object. Thus no alteration in the focus of the telescope is necessary whether we are observing the magnetic, distant fixed mark, or the sun.

The arrangement of the Observatory pattern unifilar magnetometer is shown in figs. 1 and 2. The magnet consists of a hollow steel cylinder fitted with a scale and lens as described above, and is suspended by a long thread of spun silk, which is attached at the upper end to the torsion head H. The magnet is protected from draughts by the box A, which is closed at the sides by two shutters when an observation is being taken. The telescope B serves to observe the scale.
attached to the magnet when determining the magnetic meridian, and to observe the sun or star when determining the geographical meridian.

When making a determination of declination a brass plummet having the magnet first suspended in its place, and the torsion of the fibre is taken out. The magnet having been attached, the instrument is rotated about its vertical axis till the centre division of the scale appears to coincide with the vertical cross-wire of the telescope. The two verniers on the azimuth circle having been read, the magnet is then inverted, i.e. turned through 180° about its axis, and the setting is repeated. Another setting with the magnet inverted is generally made, and then another setting with the magnet in its original position. The mean of all the readings of the verniers gives the reading on the azimuth circle corresponding to the magnetic meridian. To obtain the geographical meridian the box A is removed, and an image of the sun or a star is reflected into the telescope B by means of a small transit mirror H. This mirror can rotate about a horizontal axis which is at right angles to the line of collimation of the telescope, and is parallel to the surface of the mirror. The time of transit of the sun or star across the vertical wire of the telescope having been observed by means of a chronometer of which the error is known, it is possible to calculate the azimuth of the sun or star, if the latitude and longitude of the place of observation are given. Hence if the readings of the verniers on the azimuth circle are made when the transit is observed we can deduce the reading corresponding to the geographical meridian.

The above method of determining the geographical meridian has the serious objection that it is necessary to know the error of the chronometer with very considerable accuracy, a matter of some difficulty when observing at any distance from a fixed observatory. If, however, a theodolite, fitted with a telescope which can rotate about a horizontal axis and having an altitude circle, is employed, so that when observing a transit the altitude of the sun or star can be read off, then the time need only be known to within a minute or so. Hence in more recent patterns of magnetometer it is usual to do away with the weight method of observing and either to use a separate theodolite to observe the azimuth of some distant object, which will then act as a fixed mark when making the declination observations, or to attach to the magnetometer an altitude tube and scale circle for use when determining the geographical meridian.

The chief uncertainty in declination observations, at any rate at a fixed observatory, lies in the variable torsion of the silk suspension, as it is found that, although the fibre may be entirely freed from torsion before beginning the declination observations, yet at the conclusion of these observations a considerable amount of torsion may have appeared. Soaking the fibre with glycerine, so that the moisture it absorbs does not change so much with the hygrometric state of the air, is of some advantage, but does not entirely remove the difficulty. For this reason some observers use a thin strip of phosphor bronze to suspend the magnet, considering that the absence of a variable torsion more than compensates for the increased difficulty in handling the more fragile metallic suspension.

**Measurement of the Horizontal Component of the Earth's Field.**—The method of measuring the horizontal component which is almost exclusively used, both in fixed observatories and in the field, consists in observing the period of a freely suspended magnet, and then obtaining the angle through which an auxiliary suspended magnet is deflected by the magnet used in the first part of the experiment. By the vibration experiment, we obtain the value of the product of the magnetic moment (M) of the magnet into the horizontal component (H), while by the deflexion experiment we can deduce the value of the ratio of M to H, and hence the two combined give both M and H.

In the case of the Kew pattern uniaxial the same magnet that is used for the declination is usually employed for determining H, and for the purposes of the vibration experiment it is mounted as for the observation of the magnetic meridian. The determination is obtained by means of a chronometer, using the eye-and-ear method. The temperature of the magnet must also be observed, for which purpose a thermometer C (fig. 1) is attached to the box A. When making the deflexion experiment the magnetometer is arranged as shown in fig. 2. The auxiliary magnet has a plane mirror attached, the plane of which is at right angles to the axis of the magnet, and the settings of the ivory scale B is observed after reflection in the magnet mirror by the telescope A. The magnet K is used in the deflexion experiment is supported on a carriage L which can slide along the graduated bar D. The axis of the magnet is horizontal and at the same level as the mirror magnet, when the central division of the scale B appears to coincide with the vertical cross-wire of the telescope the axes of the two magnets are at right angles. During the experiment the mirror magnet is protected by two wooden doors which slide in grooves. What is known as the method of sines is used, for since the axes of the two magnets are always at right angles when the mirror magnet is in its zero position, the ratio M/H is proportional to the acute angle between the magnetic axis of the mirror magnet and the magnetic meridian. When conducting a deflexion experiment the deflecting magnet K is placed with its centre at 30 cm. from the mirror magnet and the angle of deflection is measured by means of an auxiliary horizontal instrument E which is attached to the scale of the magnetometer, and graduated in degrees. The same instrument is used for the vibration experiment, and the position of the auxiliary magnet is such that the two are mutually perpendicular. The auxiliary magnet is then removed, the box A is attached, and with the telescope the mirror magnet is observed, and the setting made with the graduated bar D. The zero position of the scale B is then observed when the mirror magnet is in its zero position and then removed, and when the mirror magnet is in its given position, the scale B is brought to zero, and the setting is repeated. Further, to avoid the error due to the zero of the scale D not being exactly below the mirror magnet, the support L is then removed to the west side of the magnet, and the settings are repeated. The whole process of zeroing the instrument is repeated with the mirror magnet in its zero position, and with the auxiliary magnet in its given positions.

Angles between two sets of readings are obtained by means of a reading with the declination instrument, the two sets of readings being taken with the mirror magnet in its zero position, and the scale B brought to zero when the mirror magnet is in its given position. The angular deflexion is measured with the horizontal instrument E, and the results are corrected for the effect of the earth's magnetic field. The deflexion is expressed by the equation

\[ r = \frac{H}{r} \sin \theta = 1 + \frac{Q}{r^2} + \ldots \]

where P and Q are constants depending on the dimensions and magnetic states of the two magnets. The value of P and Q can be obtained by making deflexion experiments at three distances. It is, however, possible by suitably choosing the proportions of the two magnets to make the effect equal to zero. Thus it is usual, if the magnets are of similar shape, to make the deflected magnet 0.467 of the length of the deflecting magnet, in which case Q is negligible, and the deflexion experiment is conducted at two distances the values of P being determined, as above, by C. Böring in *Terrestrial Magnatism*, 1896, i. pp. 176, and C. Chree, *Phil. Mag.*, 1904 [6], pp. 113-131.

In the case of the vibration experiment the deflexion terms have to be introduced to allow for the temperature of the magnet, for the inductive effect of the earth's field, which slightly increases the magnetic moment of the magnet, and for the torsion of the suspension fibre, as well as the rate of the chronometer. If the temperature of the magnet were always exactly the same in both the vibration and
deflexion experiment, then no correction on account of the effect of temperature in the magnetic moment would be necessary in either experiment. The fact that the moment of inertia of the magnet varies with the temperature must, however, be taken into account. In the deflexion experiment, in addition to the unfilinar magnetometer and that for the effect of temperature on the magnetic moment, a correction has to be applied for the effect of temperature on the length of the bar which supports the deflexion magnet.

See also Stewart and Gee, Practical Physics, vol. 2, containing a description of the Kew pattern unifilar magnetometer and detailed instructions for performing the experiments; C. Chree, Phil. Mag., 1901 (6), 2, p. 613, and Proc. Roy. Soc., 1899, 65, p. 375, containing a discussion of the Kew unifilar instrument and that for the effect of temperature on the magnetic moment.

**Measurements of the Magnetic Elements at Sea.**—Owing to the fact that the proportion of the earth's surface covered by sea is so much greater than the dry land, the determinations of the magnetic elements which are made from the air are of very great importance. The movements of a ship entirely preclude the employment of any instrument in which a magnet suspended by a fibre has any part, so that the unifilar is unsuited for such observations. In order to obtain the declination a pivoted magnet is used to obtain the magnetic meridian, the geographical meridian being obtained by observations on the sun or stars. A carefully made ship's compass is usually employed, though in some cases the compass card, with its attached magnets, is made reversible, so that the inclination to the zero of the card of the magnetic axis of the system of magnets attached to the card can be eliminated by reversal. In the absence of a reversible card the index correction must be determined by comparison with a unifilar magnetometer, simultaneous observations being made on shore, and these observations repeated as often as occasion permits. To determine the dip a Fox's dip circle is used. This consists of an ordinary dip circle (see EXCLINOMETER) in which the ends of the axis of the needle is pointed and read in conjunction with the scale on the card, so that the movement of the ship does not displace the needle. The instrument is, of course, supported on a gimbaled table, while the ship during the observations is kept on a fixed course. To obtain the strength of the field the method usually adopted is that known as Lloyd's method. To carry out a determination of the total force by this method the Fox dip circle has been slightly modified by E. W. Creak, and has been found to give satisfactory results on board ship. The circle is provided with two needles in addition to those used for determining the dip, one (a) an ordinary dip needle, and the other (b) a needle which has been loaded at one end by means of a small peg which fits into one of two symmetrically placed holes in the needle. The magnetism of these two needles is never reversed, and they are as much as possible protected from shock and from approach to other magnets, so that their magnetic state may remain as constant as possible. Attached to the cross-arm which carries the needle (b) is a clamp, which will hold the needle b in such a way that its plane is parallel to the vertical circle and its axis is at right angles to the line joining the two microscopes. Hence, when the microscopes are adjusted so as to coincide with the points of the dipping needle a, the axes of the two needles must be at right angles. The needle a being suspended between the jewells, and the needle b being held in the clamp, the cross-arm carrying the readingmicroscopes and the needle b is rotated till the ends of the needle a coincide with the cross-wires of the microscopes. The verniers having been read, the cross-arm is rotated so as to deflect the needle a in the opposite direction, and a new setting is taken. Half the difference between the two readings gives the angle through which the needle a has been deflected under the action of the needle b. This angle depends on the ratio of the magnetic moment of the needle b to the total force of the earth's field. It also involves, of course, the distance between the needles and the distribution of the magnetism of the needles; but this factor is determined by comparing the value given by the instrument, at a shore station, with that given by an ordinary magnetometer. Hence the above observation gives us a means of obtaining the ratio of the magnetic moment of the needle b to the value of the earth's total force. The needle b is then substituted for a, there being now no needle in the clamp attached to the microscope arm, and the difference between the reading now obtained and the dip, together with the weight added to the needle, gives the product of the moment of the needle b into the earth's total force. Hence, from the two observations the value of the earth's total force can be deduced. In an actual observation the deflecting needle would be reversed, as well as the deflected one, while different weights would be used to deflect the needle b. An account of the method of using the Fox circle for observations at sea consult the Admiralty Manual of Scientific Inquiry, p. 116, while a description of the most recent form of the circle, known as the Lloyd-Creak pattern, will be found in Terrestrial Magnetism, 1904, 6, p. 119. An attachment to the ordinary ship's compass is described by W. Wild, Zeits. für Instrumentenkunde, 1906, 26, p. 2, containing a description of a magnetometer for field use, designed by M. Eschen- hagen, which has many advantages.

**MAGNETO-OPTICS.**

The first relation between magnetism and light was discovered by Faraday, who proved that the plane of polarization of a ray of light was rotated when the ray travelled through certain substances parallel to the lines of magnetic force. This power of rotating the plane of polarization in a magnetic field has been shown to be possessed by all refracting substances, whether they are in the solid, liquid or gaseous state. The rotation by gases was established independently by H. Becquerel, and Kundt and Röntgen, while Kundt found that films of the magnetic metals, iron, cobalt, nickel, thin enough to be transparent, produced enormous rotations, these being in iron and cobalt magnetized to saturation at the rate of 200,000° per cm. of thickness, and in nickel about 80,000°. The direction of rotation is not the same in all substances, and it is positive when it is related to the direction of the magnetic force, like rotation and translation in a right-handed screw, or, what is equivalent, when it is in the direction of the electric currents which would produce a magnetic field in the same direction as that which produces the rotation, then these substances produce positive rotation. Among those that produce negative rotation are ferrous and ferric salts, ferricyanide of potassium, the salts of lanthanum, cerium and didymium, and chloride of titanium.

The magnetic metals iron, nickel, cobalt, the salts of nickel and cobalt, and oxygen (the most magnetic gas) produce positive rotation.

For the most strongly magnetizable substances the amount of rotation in a space PQ proportional to the difference between the magnetic potential at P and Q; or if $\theta$ is the rotation in PQ, $\theta_1$, $\theta_2$, the magnetic potential at P and Q, then $\theta = \theta_2 - \theta_1$. The main line of research was to determine some new reducting substance, the wave length of the light, and the temperature. The following are the values of R (when the rotation is expressed in circular measure) for the D line and a temperature of 18°C:—

The variation of Verdet's constant with temperature has been determined for carbon bisulphide and water by Rodger and Watson (loc. cit.). They find if \( R_1, R_2 \) are the values of Verdet's constant at \( T^1 \)C. and \( O^0 \) C. respectively, then for carbon bisulphide \( R_2 = R_0 (1 - 0.0316601) \), and for water \( R_2 = R_0 (1 - 0.00000350 - 0.00000350^2) \).

For the magnetic metals Kundt found that the rotation did not increase so rapidly as the magnetic force, but that as this force was increased the rotation reached a maximum value. This suggests that the rotation is proportional to the intensity of magnetization, and not to the magnetic force.

The amount of rotation in a given field depends greatly upon the wave length of the light: the shorter the wave length the greater the rotation, the rotation varying a little more rapidly than the inverse square of the wave length. Kundt \(^1\) has compared in the cases of carbon bisulphide and cresyocrot the rotation given by the formula

\[
\theta = me \frac{R}{\lambda} \left(-\frac{dI}{dx}\right)
\]

with those actually observed; in this formula \( \theta \) is the angular rotation of the plane of polarization, \( m \) a constant depending on the medium, \( \lambda \) the wave length of the light in air, and \( x \) the index of refraction in the medium. Verdet found that, though the agreement is fair, the differences are greater than can be explained by errors of experiment.

Verdet \(^2\) has shown that the rotation of a salt solution is the sum of the rotations due to the salt and the solvent; thus, by mixing a salt which produces negative rotation with water which produces positive rotation, it is possible to get a solution which does not exhibit any rotation. Such solutions are not in general magnetically neutral. By mixing diamagnetic and paramagnetic substances we can get magnetically neutral solutions, which, however, produce a finite rotation of the plane of polarization. The relation of the magnetic rotation to chemical constitution has been studied in great detail by Perkin, \(^3\) Wachsmuth, \(^4\) Jahn \(^5\) and Schönrock. \(^6\)

The rotation of the plane of polarization may conveniently be regarded as denoting that the velocity of propagation of circular-polarized light travelling along the lines of magnetic force depends upon the direction of rotation of the ray, the velocity when the rotation is related to the direction of the magnetic force, like rotation and translation on a right-handed screw being different from that for a left-handed rotation. A plane-polarized ray may be regarded as composed of two oppositely circularly-polarized rays, and as these travel along the lines of magnetic force with different velocities, the one will gain or lose in phase on the other, so that when they are again compounded they will correspond to a plane-polarized ray, but in consequence of the change of phase the plane of polarization will have given an original plane of rotation. The rotation of the plane of polarization will have given an original plane of rotation.

Reflection from a Magnet.—Kerr \(^7\) in 1817 found that when plane-polarized light is incident on the pole of an electromagnet, polished so as to act like a mirror, the plane of polarization of the reflected light is rotated by the magnet. Further experiments on this phenomenon have been made by Righi, \(^8\) Kundt, \(^9\) Du Bois, \(^10\) Sissingh, \(^11\) Hall, \(^12\) Hurton, \(^13\) Kaz \(^14\) and Zeeman. \(^15\)

The simplest case is when the incident plane-polarized light falls normally on the pole of an electromagnet. When the magnet is not excited the reflected ray is plane-polarized; when the magnet is excited the plane of polarization is rotated through a small angle, the direction of rotation being opposite to that of the currents exciting the pole. Righi found that the reflected light was slightly elliptically polarized, the axes of the ellipse being of very unequal magnitude. A piece of gold-leaf placed over the pole entirely stops the rotation, showing that it is not produced in the air near the pole. Rotation takes place from magnetized nickel and cobalt as well as from iron, and is in the same direction (Hall). Righi has shown that the rotation at reflection is greater for long waves than for short, whereas, as has been seen, the Faraday rotation is greater for short waves than for long. The rotation for different coloured light from iron, nickel, cobalt and magnetite has been measured by Du Bois; in magnetite the direction of rotation is opposite to that of the other metals. When the light is incident obliquely and not normally on the polished pole of an electromagnet, it is elliptically polarized after reflection, even when the plane of polarization is parallel or at right angles to the plane of incidence.

According to Righi, the amount of rotation when the plane of polarization of the incident light is perpendicular to the plane of incidence reaches a maximum when the angle of incidence is between \( 44^\circ \) and \( 68^\circ \), while when the light is polarized in the plane of incidence the rotation steadily decreases as the angle of incidence is increased. The rotation when the light is polarized in the plane of incidence is always less than when it is polarized at right angles to that plane, except when the incidence is normal, when the two rotations are of course equal.

Reflection from Tangentially Magnetized Iron.—In this case Kerr \(^2\) found: (1) When the plane of incidence is perpendicular to the lines of magnetic force, no rotation of the reflected light is produced by magnetization: (2) no rotation is produced when the light is incident normally: (3) when the incidence is oblique, the lines of magnetic force being in the plane of incidence, the reflected light is elliptically polarized after reflection, and the axes of the ellipse are not in and at right angles to the plane of incidence. When the light is polarized in the plane of incidence, the rotation is at all angles of incidence in the opposite direction to that of the currents which would produce a magnetic field of the same sign as the magnet. When the light is polarized at right angles to the plane of incidence, the rotation is in the same direction as the direction of the magnetic force, but its magnitude may be regarded as zero. Additional data have been given by Sissingh, \(^16\) Hurton, \(^17\) Voight, \(^18\) Kettel, \(^19\) van Loghem, \(^20\) Potier, \(^21\) Basset, \(^22\) Goldhammer, \(^23\) Drude, \(^24\) J. T. Thomson, \(^25\) and Leatham; \(^26\) for a critical discussion of many of these theories we refer the reader to Larmor's \(^27\) British Association Report. Most of these theories have proceeded on the plan of adding to the expression for the electromagnetic force terms indicating a force similar in character to that discovered by Hall (see MAGNETISM) in metallic conductors carrying a current in a magnetic field, i.e., an electromagnetic force at right angles to the plane containing the magnetic force and the electric current, and proportional to the sine of the angle between these vectors. The introduction of a term of this kind gives rotation of the plane of polarization by transmission through all the substances, and by reflection from magnetized metals, and shows a fair agreement with the theoretical and experimental results. The simplest way of treating the questions seems, however, to be to go to the equations which represent the propagation of a wave travelling through a medium containing ions. A moving ion in a magnetic field will be acted upon by a mechanical force which is at right angles to its direction of motion, and also to the magnetic force, and is equal per unit charge to the product of these two vectors and the sine of the angle between them. For the sake of brevity we will take the special case of a wave travelling parallel to the magnetic force in the direction of the axis of

Then supposing that all the ions are of the same kind, and that there are \( n \) of these each with mass \( m \) and charge \( e \) per unit volume, the equations representing the field are (see ELECTRIC WAVES):——

\[
K_e \frac{dX_e}{dt} + \frac{4\pi ne_p}{c} \frac{dX_e}{dt} - \frac{dQ}{dt}
\]

\[
\frac{d\Phi}{dx} = \frac{dQ}{dt}
\]

\[
K_e \frac{dY_p}{dt} + \frac{4\pi n e_p}{c} \frac{dY_p}{dt} - \frac{dQ}{dt}
\]

\[
\frac{d\Phi}{dx} = \frac{dQ}{dt}
\]

\[
\frac{dH_e}{dt} + R_1 \frac{dH_e}{dt} + \alpha = (X_e + \frac{4\pi ne_p}{c} e + H_e) \frac{dX_e}{dt}
\]

\[
\frac{dH_e}{dt} + R_1 \frac{dH_e}{dt} + \alpha = (Y_e + \frac{4\pi ne_p}{c} e - H_e) \frac{dY_e}{dt}
\]

where \( H \) is the external magnetic field, \( X, Y \) the components of the part of the electric force in the wave not due to the charges on the atoms, \( a, b \) the components of the magnetic force, \( \xi, \eta \)}
the co-ordinates of an ion, \( R \), the coefficient of resistance to the motion of the ions, and \( a \) the force at unit distance tending to bring the ion back to its position of equilibrium, \( K_0 \) the specific inductive capacity of a vacuum. If the variables are proportional to \( e^{i\varphi r} \) we find by substitution that \( q \) is given by the equation
\[
q^2 - Kq^2 = m^2 \left( e^{i\varphi r} - e^{-i\varphi r} \right)
\]
where
\[
P = (a - 2e^{i\varphi r}) - R + E - m^2,
\]
or, by neglecting \( R \),
\[
P = m^2 (s^2 - p^2),
\]
where \( s \) is the period of the free ions. If \( q_1, q_2 \) are the roots of this equation, then corresponding to \( q_1 \) we have \( X_1 = X_0 \) and to \( q_2 \), \( X_2 = -X_0 \). We thus get two oppositely circular-polarized rays travelling with the velocities \( p/q_1 \) and \( p/q_2 \) respectively. Hence if \( v_1, v_2 \) are these velocities, and \( \theta \) the velocity when there is no magnetic field, we obtain, if we neglect terms in \( \Phi^2 \),
\[
\begin{align*}
\frac{1}{v_1} &= \frac{s^2 - m^2}{s^2 + m^2} n_{1} + m_{1} \\
\frac{1}{v_2} &= \frac{s^2 - m^2}{s^2 + m^2} n_{2} - m_{2}
\end{align*}
\]
The rotation \( r \) of the plane of polarization per unit length
\[
r = \frac{1}{p} \left( \frac{1}{v_1} - \frac{1}{v_2} \right) m_{p} = \frac{s^2 - m^2}{s^2 + m^2} n_{p},
\]
where \( \lambda \) is the wave length. This is equivalent to (2) if \( \mu \) is given by \( (\lambda) \). He has shown that this expression is in good agreement with experiment. The sign of \( r \) depends on the sign of \( \epsilon \), hence the rotation due to negative ions would be opposite to that for positive. For the great majority of substances the sign of rotation is that corresponding to the negative ion. We note from the equation that the rotation is very large for such a value of \( \psi \) as makes \( P = 0 \); this value corresponds to a free period of the ions, so that the rotation ought to be very large in the neighbourhood of an absorption band. This has been verified for sodium vapour by Macaluso and Corbino.\(^{43}\)

If plane-polarized light falls normally on a plane face of the medium containing the ions, then if the electric force in the incident wave is parallel to \( x \) and is equal to the real part of \( A e^{i(\varphi r)} \), if the reflected beam in which the electric force is parallel to \( x \) is represented by \( B e^{i(\varphi r)} \) and the reflected beam in which the electric force is parallel to the axis of \( y \) by \( C e^{i(\varphi r)} \), then the condition that the magnetic force parallel to the surface is continuous, and that the electric forces parallel to the surface in the air are continuous with \( X_0 \), \( X_2 \) in the medium, give
\[
\frac{A}{q^2 + a^2} + \frac{B}{q^2 + a^2} = \frac{C}{q^2 + a^2} = \frac{\epsilon}{c}
\]
or, approximately, since \( q_1 \) and \( q_2 \) are nearly equal,
\[
\frac{C}{B} = \frac{q^2 - a^2}{q^2} = \left( \mu^2 - 1 \right) \frac{1}{P}
\]
Thus in transparent bodies for which \( \mu \) is real, \( C \) and \( B \) differ in phase by \( \pi/2 \), and the reflected light is elliptically polarized, the major axis of the ellipse being in the plane of polarization of the incident light, so that in this case the rotation is an elliptical polarization; when there is strong absorption so that \( \mu \) contains an imaginary term, \( C/B \) will contain a real part so that the reflected light will be elliptically polarized, but the major axis is no longer in the plane of polarization of the incident light; we should thus have a rotation of the plane of polarization superposed on the elliptic polarization.

Zeeman's Effect.—Faraday, after discovering the effect of a magnetic field on the plane of polarization of light, made numerous experiments to see if such a field influenced the nature of the light emitted by a luminous body, but without success. In 1885 Fizeau,\(^{44}\) a Belgian physicist, noticed that the spectrum of a sodium flame was changed slightly in appearance by a magnetic field; but his observation does not seem to have attracted much attention, and was probably ascribed to secondary effects.

In 1896 Zeeman\(^{45}\) saw a distinct broadening of the lines of lithium and sodium when the flames containing salts of these metals were between the poles of a powerful magnet; following up this observation, he obtained some exceedingly remarkable and interesting results, of which those observed with the blue-green cadmium line may be taken as typical. He found that in a strong magnetic field, when the lines of force are parallel to the direction of propagation of the light, the line is split up into a doublet, the constituents of which are on opposite sides of the undisturbed position of the line, and that the light in the constituents of this doublet is circularly polarized, the rotation in the two lines being in opposite directions. When the magnetic force is at right angles to the direction of propagation of the light, the line is resolved into a triplet, of which the middle line occupies the same position as the undisturbed line; all the constituents of this triplet are plane-polarized, the plane of polarization of the middle line being at right angles to the magnetic force, while the outside lines are polarized on a plane parallel to the lines of magnetic force. A great deal of light is thrown on this phenomenon by the following considerations due to H. A. Lorentz.\(^{46}\)

Let us consider an ion attracted to a centre of force by a force proportional to the distance, and acted on by a magnetic force parallel to the axis of \( z \); then if \( m \) is the mass of the particle and \( e \) its charge, the equations of motion are
\[
\begin{align*}
\frac{dx}{dt} &= -e \mathbf{E} z - e \mathbf{B} \times \mathbf{P} \\
\frac{dy}{dt} &= e \mathbf{E} x + e \mathbf{B} \times \mathbf{P} \\
\frac{dz}{dt} &= e \mathbf{E} \\
\frac{dP_x}{dt} &= -e \mathbf{E} z \\
\frac{dP_y}{dt} &= e \mathbf{E} x \\
\frac{dP_z}{dt} &= 0
\end{align*}
\]
The solution of these equations is
\[
\begin{align*}
x &= A \cos (p_1 t + \beta_1) + B \cos (p_2 + \beta_2) \\
y &= A \sin (p_1 t + \beta_1) - B \sin (p_2 + \beta_2) \\
z &= C \cos (p_2 + \beta_2)
\end{align*}
\]
Thus the motion of the ion on the \( xy \) plane may be regarded as made up of two circular motions in opposite directions described with frequencies \( p_1 \) and \( p_2 \) respectively, while the motion along \( z \) is a simple harmonic motion, which is the frequency for all the vibrations when \( H = 0 \). Now suppose that the cadmium line is due to the motion of such an ion; then if the magnetic force is along the direction of propagation, the vibration in this direction has its period unaltered, but since the direction of vibration is perpendicular to the wave front, it does not give rise to light. Thus we are left with the two circular motions in the wave front with frequencies \( p_1 \) and \( p_2 \) giving the circularly polarized constituents of the doublet. Now suppose the magnetic force is at right angles to the direction of propagation of the light; then the vibration parallel to the magnetic field being in the wave front produces luminous effects and gives rise to a plane-polarized ray of undisturbed period (the middle line of the triplet), the plane of polarization being at right angles to the magnetic force. The components in the wave-front of the circular orbits at right angles to the magnetic force will be rectilinear motions of frequency \( p_1 \) and \( p_2 \) at right angles to the magnetic force—so that they will produce plane-polarized light, the plane of polarization being parallel to the magnetic force; these are the outer lines of the triplet.

If Zeeman's observations are interpreted from this point of view, the directions of rotation of the circularly-polarized light in the doublet observed along the lines of magnetic force show that the ions which produce the luminous vibrations are negatively electrified, while the measurement of the charge of frequency due to the magnetic field shows that \( e/m \) is of the order \( 10^7 \). This result is of great interest, as this is the order of the value of \( e/m \) in the negatively electrified particles which constitute the Cathode Rays (see CONDUCTION, ELECTRIC III. Through Gases). Thus we infer that the cathode particles are found in bodies, even where not subject to the action of intense electrical fields, and are in fact an ordinary constituent of the molecule. Similar particles are found near an incandescent wire, and also near a metal plate illuminated by ultra-violet light. The value of \( e/m \) deduced from the Zeeman effect ranges from \( 10^7 \) to \( 3 \times 10^7 \); the value of \( e/m \) for the particle in the cathode rays is \( 1.7 \times 10^7 \). The majority of the determinations of \( e/m \) from the Zeeman effect give numbers larger than this, the maximum being about twice this value.
A more extended study of the behaviour of the spectroscope lines has afforded examples in which the effects produced by a magnet are more complicated than those we have described, indeed the simple cases are much less numerous than the more complex. Thus Preston and Runge have shown that under the action of a transverse magnetic field one of the D lines splits up into four, and the other into six lines; Preston has given many other examples of these quartets and sextets, and has shown that the change in the frequency, which, according to the simple theory indicated, should be the same for all lines, actually varies considerably from one line to another, many lines showing no appreciable displacement. The splitting up of a single line into a quartet or sextet indicates, from the point of view of the ion theory, that the line must have its origin in a system consisting of more than one ion. A single ion having only three degrees of freedom can only have three periods. When there is no magnetic force acting on the ion these periods are equal, but though under the action of a magnetic force they are separated, their number cannot be increased. When therefore we get four or more lines, the inference is that the system giving the lines must have at least four degrees of freedom, and therefore must consist of more than one ion. The theory of a system of ions mutually influencing each other shows, as we should expect, that the effects are more complex than in the case of a single ion, and that the change in the frequency is not necessarily the same for all systems (see J. J. Thomson, Proc. Camb. Phil. Soc. 13, p. 39). Preston and Runge and Paschen have proved that, in some cases at any rate, the change in the frequency of the different lines is of such a character that they can be grouped into series such that each line in the series has the same change in frequency for the same magnetic force, and, moreover, that homologous lines in the spectra of different metals belonging to the same group have the same change in frequency.

A very remarkable case of the Zeeman effect has been discovered by H. Becquerel and Deslandres (Comptes rendus, 127, p. 18). They found lines in iron when the most difficult components are those polarized in the plane at right angles to the magnetic force. On the simple theory the light polarized in this way is not affected. Thus the behaviour of the spectrum in the magnetic field promises to throw great light on the nature of radiation, and perhaps on the constitution of the elements. The study of these effects has been greatly facilitated by the invention of Michelson of the echron spectroscope.

There are some interesting phenomena connected with the Zeeman effect which are more easily observed than the effect itself. Thus Cotton found that if we have two Bunsen flames, A and B, coloured by the same salt, the absorption of the light of one by the other is diminished if either is placed between the poles of a magnet; this is at once explained by the Zeeman effect, for the times of vibration of the molecules in the magnetic field are not the same as those of the other flame, and thus the absorption is diminished. Similar considerations explain the phenomenon observed by Egoroff and Georgiewsky, that the absorption of light by benzene is decreased on being irradiated by an incandescent filament having an axial magnetic field.

MAGNOLIA

The typical genus of the botanical order Magnoliaceae, named after Pierre Magnol (1638-1715), professor of medicine and botany at Montpellier. It contains about twenty species, distributed in Japan, China and the Himalayas, as well as in North America.

Magnolias are trees or shrubs with deciduous or rarely evergreen foliage. They bear conspicuous and often large, fragrant, white, rose or purple flowers. The sepals are three in number, the petals six to twelve, in two or four series of three each, with the stamens and carpels being numerous. The fruit consists of a number of follicles which are borne on a more or less conical receptacle, and dehisce along the outer edge to allow the scarlet or brown seeds to escape; the seeds however remain suspended by a long slender thread (the funicle). Of the old-world species, the earliest in cultivation appears to have been *M. yulan* (or *M. conspicua*) of China, of which the buds were preserved, as well as used medicinally and to season rice; together with the greenhouse species, *M. fuscata*, it was transported to Europe in 1789, and thence to North America, and is now cultivated in the Middle States. There are many fine forms of *M. conspicua*, the best being *soulangeana*, white tinted with purple, *Lennei* and *stricta*. Of the Japanese magnolias, *M. kobus* and the purple-flowered *M. obovata* were met with by Kaemper in 1602, and were introduced into England in 1700 and 1804 respectively. *M. pumila*, the dwarf magnolia, from the mountains of Amboyna, is nearly evergreen and bears deliciously scented flowers; it was introduced in 1786. The Indian species are three in number, *M. globosa*, allied to *M. conspicua* of Japan, *M. sphenocarpa*, and, the most magnificent of all magnolias, *M. campbellii*, which forms a conspicuous feature in the scenery and vegetation of Darjeeling. It was discovered by Dr Griffith in Bhutan, and is a large forest tree, abounding on the outer ranges of Sikkim, so to 150 ft. high, and from 6 to 12 ft. in girth. The flowers are 6 to 10 in. across, appearing before the leaves, and vary from white to a deep rose colour.

The first of the American species brought to Europe (in 1688 by John Banister) was *M. glauca*, a beautiful evergreen species about 15 ft. high with obuse leathery leaves, blue-green above, silvery underneath, and globular flowers varying from creamy white to pale yellow with age. It is found in low situations near the sea from Massachusetts to Louisiana—more especially in New Jersey and the Carolinas. *M. acuminata*, the so-called "cucumber tree," from the resemblance of the young fruits to small cucumbers, ranges from Pennsylvania to Carolina. The
wood is yellow, and used for bowls; the flowers, 3 to 4 in. across, are glaucous green tinted with yellow. It was introduced into England from Virginia about 1736. *M. tripetala* (or *M. umbrella*), is known as the "umbrella tree" from the arrangement of the leaves at the ends of the branches resembling somewhat that of the ribs of an umbrella. The flowers, 5 to 8 in. across, are white and have a strong but not disagreeable scent. It was brought to England in 1752. *M. Fraseri* (or *M. auriculata*),

white starry flowers as early as February and March on the leafless stems; and *M. Watsoni*, another fine deciduous Japanese bush or small tree with very fragrant pure white flowers 5 to 6 in. across.

The tulip tree, *Liriodendron tulipifera*, a native of North America, frequently cultivated in England, is also a member of the same family. It reaches a height of over 100 ft. in a native condition, and as much as 60 to 80 ft. in England. It resembles the plane tree somewhat in appearance, but is readily recognized by lobed leaves having the apical lobe truncated, and by its soft green and yellow tulip-like flowers—which however are rarely borne on trees under twenty years of age.

For a description of the principal species of magnolia under cultivation see J. Weathers, Practical Guide to Garden Plants, pp. 174 seq.; and for a detailed account of the American species see C. S. Sargent, Silva of North America, vol. i.

**MAGNUS, HEINRICH GUSTAV** (1803–1870), German chemist and physicist, was born at Berlin on the 2nd of May 1803. His father was a wealthy merchant; and of his five brothers one, Eduard (1790–1872), became a celebrated painter. After studying at Berlin, he went to Stockholm to work under Berzelius, and later to Paris, where he studied for a while under Gay-Lussac and Thénard. In 1831 he returned to Berlin as lecturer on technology and physics at the university. As a teacher his success was rapid and extraordinary. His lucid style and the perfection of his experimental demonstrations drew to his lectures a crowd of enthusiastic scholars, on whom he impressed the importance of applied science by conducting them round the factories and workshops of the city; and he further found time to hold weekly "colloquies" on physical questions at his house with a small circle of young students. From 1827 to 1833 he was occupied mainly with chemical researches, which resulted in the discovery of the platino-ammonium compounds ("Magnus's compounds") of sulphonic, ethereal, and hydriodic acids and their salts, and in conjunction with C. F. Ammendiller, of periodic acid. Among other subjects at which he subsequently worked were the absorption of gases in blood (1837–1845), the expansion of gases by heat (1841–1844), the vapour pressures of water and various solutions (1844–1854), thermo-electricity (1851), electrolysis (1856), induction of currents (1858–1861), conduction of heat in gases (1860), and polarization of heat (1866–1868). From 1861 onwards he devoted much attention to the question of diathermy in gases and vapours, especially to the behaviour in this respect of dry and moist air, and to the thermal effects produced by the condensation of moisture on solid surfaces.

In 1834 Magnus was elected extraordinary, and in 1845 ordinary professor at Berlin. He was three times elected dean of the faculty, in 1847, 1858 and 1863; and in 1861, rector magnificus. His great reputation led to his being entrusted by the government with several missions; in 1865 he represented Prussia in the conference called at Frankfort to introduce a uniform metric system of weights and measures into Germany. For forty-five years his labour was incessant; his first memoir was published in 1825 when he was yet a student; his last appeared shortly after his death on the 4th of April 1870. He married in 1840 Bertha Humbolt, of a French Huguenot family settled in Berlin, by whom he left a son and two daughters.

See Allgemeine deutsche Bibl. The Royal Society's Catalogue enumerates 84 papers by Magnus, most of which originally appeared in Foiggendoff's Annalen.

**MAGNY, CLAUDE DRIGON, MARQUIS DE** (1707–1879), French heraldic writer, was born in Paris. After being employed for some time in the postal service, he devoted himself to the study of heraldry and genealogy, his work in this direction being rewarded by Pope Gregory XVI. with a marquessate. He founded the French college of heraldry, and wrote several works on heraldry and genealogy, of which the most important were *Archives nobiliares universelles* (1843) and *Livre d'or de la noblesse de France* (1844–1852). His two sons, Edouard Drigon and Achille Ludovice Drigon, respectively came and vicomte de Magny, also wrote several works on heraldry.
MAGO—MAGYARS

393

MAGO, the name of several Carthaginians. (1) The reputed founder of the military power of Carthage, fl. 550-300 B.C. (Justin xviii. 7, xix. 1). (2) The youngest of the three sons of Hamilcar Barca. He accompanied Hannibal into Italy, and held important commands in the great victories of the first three years. After the battle of Cannae (216 B.C.) he sailed to Carthage to report the successes gained. He was about to return to Italy with strong reinforcements for Hannibal, when the government ordered him to go to the aid of his other brother, Hasdrubal, who was hard pressed in Spain. He carried on the war there with varying success in concert with the two Hasdrubals until, in 209, his brother marched into Italy to help Hannibal. Mago remained in Spain with Hasdrubal, the son of Gisco. In 207 he was defeated by M. Junius Silanus, and in 206 the combined forces of Mago and Hasdrubal were scattered by Scipio Africanus in the decisive battle of Silpi. Mago maintained himself for some time in Gades, but afterwards received orders to carry the war into Liguria. He wintered in the Balearic Isles, where the harbour Portus Magonis (Port Mahon) still bears his name. Early in 204 he landed in Liguria, where he maintained a desultory warfare till in 203 he was defeated in Cisalpine Gaul by the Roman forces. Shortly afterwards he was ordered to return to Carthage, but on the voyage home he died of wounds received in battle.

See Polybius iii.; Livy xxi.–xxiii.; xxvii., chs. 23-37; xxx., xxx.; Appian, Hispanica, 25-37; T. Friedrich, Biographie des Barbieren Mago; H. Lechmann, Der Angriff der drei Barbiren auf Italien (Leipzig, 1897); and further J. P. Mahaffy, in Hermathena, viii. 29-36 (1890).

(3) The name of Mago is also attached to a great work on agriculture which was brought to Rome and translated by order of the senate after the destruction of Carthage. The book was regarded as a standard authority, and is often referred to by later writers.

See Pliny, Nat. Hist. xviii. 5; Columella, i. 1; Cicero, De oratore, i. 58.

MAGPIE, or simply Prie (Fr. pie), the prefix being the abbreviated form of a human name (Margaret?), a bird once common throughout Great Britain, though now nearly everywhere scarce. Its pilling habits have led to this result, yet the injuries it causes are exaggerated by common report; and in many countries of Europe it is still the trotated or even the cherished neighbour of every farmer, as it formerly was in England if not in Scotland also. It did not exist in Ireland in 1617, when Fynes Morison wrote his Itinerary, but it had appeared there within a hundred years later, when Swift mentions its occurrence in his Journal to Stella, 9th July 1711. It is now common enough in that country, and there is a widespread but unfounded belief that it was introduced by the English out of spite. It is a species that when not molested is extending its range, as J. Wolsey ascertained in Lapland, where within the last century it has been gradually pushing its way along the coast and into the interior from one fishing-station or settler’s house to the next, as the country has been peopled.

Since the persecution to which the pie has been subjected in Great Britain, its habits have altered greatly. It is no longer the merry, saucy hanger-on of the homestead, but is become the suspicious thief, shunning the gaze of man, and knowing that danger may lurk in every bush. Hence opportunities of observing it fall to the lot of few, and many persons know it only as a curtailed captive in a wicker cage, where its vivacity and natural beauty are lessened or wholly lost. At large few European birds possess greater beauty, the pure white of its scapulars and inner web of the flight-feathers contrasting vividly with the deep glossy black on the rest of its body and wings, while its long tail is lustrous with green, bronze, and purple reflections. The pie’s nest is a wonderfully ingenious structure, placed either in high trees or low bushes, and so massively built that it will stand for years. Its foundation consists of stout sticks, turf and clay, wrought into a deep, hollow cup, plastered with earth, and lined with fibres; but around this is erected a firmly interwoven, basket-like outwork of thorny sticks, forming a dome over the nest, and leaving but a single hole in the side for entrance and exit, so that the whole structure is rendered almost impregnable. Herein are laid from six to nine eggs, of a pale bluish-green freckled with brown and blotched with ash-colour. Superstition as to the appearance of the pie still survives even among many educated persons, and there are several versions of a rhyming adage as to the various turns of luck which its presenting itself, either alone or in company with others, is supposed to betoken, though all agree that the sight of a single pie presages sorrow.

The pie belongs to the same family of birds as the crow, and is the Coreus pica of Linnaeus, the Pica caudata, P. melanoleuca, or P. rustica of modern ornithologists, who have recognized it as forming a distinct genus, but the number of species thereto belonging has been a fruitful source of discussion. Examples from the west of Spain differ slightly from those inhabiting the rest of Europe, and in some points more resemble the P. montanus of north-western Africa; but that species has a patch of bare skin of a fine blue colour behind the eye, and much shorter wings. No fewer than five species have been discriminated from various parts of Asia, extending to Japan; but only one of them, the P. leucoptera of Turkestan and Tibet, has of late been admitted as valid. In the west of North America, and in some of its islands, a pie is found which extends to the upper valleys of the Missouri and the Yellowstone, and has long been thought entitled to specific distinction as P. hudsoni; but its claim thereto is now disallowed by some of the best ornithologists of the United States, and it can hardly be deemed even a geographical variety of the Old-World form. In California, however, there is a permanent race if not a good species, P. nuttalli, easily distinguishable by its yellow bill and the bare yellow skin round its eyes; on two occasions in the year 1867 a bird apparently similar was observed in Great Britain (Zoologist, ser. 2, p. 706, 1076.)

MAGWE, a district in the Minbu division of Upper Burma. Area, 2913 sq. m.; pop. (1901), 246,708, showing an increase of 12-38% in the decade. Magwe may be divided into two portions: the low, flat country in the Taungdwingyi subdivision, and the undulating high ground extending over the rest of the district. In Taungdwingyi the soil is rich, loamy, and extremely fertile. The plain is about 45 m. from north to south. At its southern extremity it is about 30 m. wide, and lessens in width to the north till it ends in a point at Natmauk. On the east are the Pegu Yomas, which at some points reach a height of 1500 ft. A number of streams run westwards to the Irrawaddy, of which the Yin and the Pin, which form the northern boundary, are the chief. The only perennial stream is the Yanpê. Rice is the staple product, and considerable quantities are exported. Sesanum of very high quality, maize, and millet are also cultivated, as well as cotton in patches here and there over the whole district.

In this district are included the well-known Yenanyaung petroleum wells. The state oil field has now been leased to the Burma Oil Company. The amount of oil-bearing land is estimated at 20,708 sq. m. and the portion not leased to the company has been demarcated into blocks of 1 sq. m. and offered on lease. The remaining land belongs to hereditary Burmese owners called twins, who dig wells and extract their oil by the rope and pulley system as they have always done. Lacquered wood trays, bowls and platters, and cartwheels, are the only manufactures of any note in the district.

The annual rainfall averages about 27 inches. The maximum temperature frequently rises to 106° F. in the day, and falls to an average minimum of 53° and 54° in the cold season. The town of Magwe is the headquarters of the division; pop. (1901), 6232. It is diagonally opposite Minbu, the headquarters of the division, on the right bank of the Irrawaddy.

MAGYARS, the name of the dominant race in Hungary, or Hungarians proper. Though they have become physically assimilated to the western peoples, they belong in origin and language to the Fimo-Ugrian (q.v.) division of the Ural-Altaic race. They form barely half of the population of Hungary, but are by far the largest single and most compact of all its racial groups.
MAHABALESHWAR—MAHANADI

Magyar is the official language of Hungary, the official name of which (Magyarország, or "country of the Magyars") enshrines the Magyar claim to predominance. While all Magyars are properly Hungarians, all Hungarians are not necessarily Magyars. "Hungarian" may be used as a generic term covering all the various races of Hungary, while "Magyar" is strictly specific to a single group. The Magyars themselves, indeed, sometimes apply the name Magyarország to Hungary "proper," excluding Croatia-Slavonia, the whole kingdom being called Magyarnövodalom, the Magyar monarchy or realm. See Hungary.

MAHABALESHWAR, or Malcolmpeeth, a hill station in Satara district, and the principal sanatorium in the Bombay presidency, India. Pop. (1901), 5290. It is reached by carriage from Wathar railway station (39 m.) or by motor car from Poona (119 m.). Mahabaleshwar occupies the summit of a ridge of the Western Ghats, with a general elevation of 4500 ft. above sea-level. It was established in 1828 by Sir John Malcolm, governor of Bombay, who obtained the site from the raja of Satara in exchange for another patch of territory. The superior elevation of Mahabaleshwar renders it much cooler than Matheran (2460 ft.), a sanatorium about 50 m. E. of Bombay, but its heavy rainfall (292 in. annual average) makes it almost uninhabitable during the rainy season. The mean annual temperature is 67°F. In the hottest month (March–April) an extreme of a little over 90° is reached during the day. Mahabaleshwar forms the retreat usually during spring, and occasionally in autumn, of the governor of Bombay, and the chief officers of his establishment, and has the usual public buildings of a first-class sanatorium.

MAHAFFY, JOHN PENTLAND (1839– ), Irish classical scholar, was born in Switzerland on the 12th of July 1839. He received his early education in Switzerland and Germany, and at Trinity College, Dublin, where he held the professorship of ancient history. Mahaffy, a man of great versatility, published numerous works, some of which, especially those dealing with what may be called the Silver Age of Greece, became standard authorities. The following are a few: History of Classical Greek Literature (4th ed., 1903 seq.); Social Life in Greece from Homer to Menander (4th ed., 1903); The Silver Age of the Greek World (1906); The Empire of the Ptolemies (1886); Greek Life and Thought from Alexander to the Roman Conquest (2nd ed., 1896); The Greek World under Roman sway from Polybius to Plutarch (1890). His translation of Kuno Fischer's Commentary on Kant (1866) and his own exhaustive analysis, with elucidations, of Kant's critical philosophy are of great value. He also edited the Petrie papyri in the Cunningham Memoirs (3 vols. 1861–1905).

MAHALAT, a province of central Persia, situated between Kashan and Irak. Pop. about 20,000; yearly revenue about £2500. Until 1890 it was one of the five "central provinces" (the other four being Irak, Ferahan, Kezzar, and Savah), which were under a governor appointed by the shah; since then it has formed part of the Isfahan government. It is traversed by the Anar river, which runs through the city of Anar, and is divided into upper and lower, or Ryivan and Zanjirvan, and twenty-two towns. It was known in former times as Anar, the Anarus of Pettinger's tables. The city, capital of the province, is situated at an elevation of 3850 ft. in 33° 51' N., 56° 30' E.; pop. about 10,000.

MAHAN, ALFRED THAYER (1840– ), American naval officer and historian, was born on the 27th of September 1840 at West Point, New York. His father, Dennis Hart Mahan (1802–1871) was a professor in the military academy, and the author of textbooks on civil and military engineering. The son graduated at the naval academy in 1859, became lieutenant in 1861, served on the "Congress," and on the "Pocahontas," "Seminole," and "James Adger" during the Civil War, and was instructor at the naval academy for a year. In 1864 he was made lieut.-commander, commander in 1872, captain in 1885. Meanwhile he saw service in the Gulf of Mexico, the South Atlantic, the Pacific, and Asia, and did shore duty at Boston, New York, and Annapolis. In 1886–89 he was president of the naval war college at Newport, Rhode Island. Between 1889 and 1892 he was engaged in special service for the bureau of navigation, and in 1893 was made commander of the "Chicago," of the European squadron. In 1896 he retired from active service, but was a member of the naval board of strategy during the war between the United States and Spain. He was a member of the peace congress at the Hague in 1899. This long and varied service gave him extensive opportunities for observation, which he supplemented by constant study of naval authorities and reflection on the interpretation of the problems of maritime history. His first book was a modest and compact story of the affairs in The Gulf and Inland Waters (1883), in a series of volumes by various writers, entitled The Navy in the Civil War; in 1890 he suddenly acquired fame by the appearance of his masterly work entitled The Influence of Sea Power upon History, 1660–1783. Having been impressed by the failure of historians to allow for the influence of sea power in struggles between nations, he was led to make prolonged investigations of this general theme (see SEA POWER). The reception accorded the volume was instant and hearty; in England, in particular, it was deemed almost an epoch-making work, and was praised by naval specialists, cabinet ministers and journalists, as well as by a large part of the general public. It was followed by The Influence of Sea Power upon the French Revolution and Empire (2 vols. 1892); The Life of Nelson, the Embodiment of the Sea Power of Great Britain (1897); and Sea Power in its Relations to the War of 1812 (1905). The author's general aim in these works—some of which have been translated into French, German and Japanese—was to make the consideration of maritime matters paramount to that of military, political or economic movements, without, however, as he himself says "divorcing them from their surroundings of cause and effect in general history, but seeking to show how they modified the latter, and were modified by them." He selected the year 1660 as the beginning of his narrative, as being the date when the sailing-ship era, with its distinctive features, had fairly begun. The series as a whole has been accepted as finally authoritative, supplanting its predecessors of similar aim, and almost—in the words of Theodore Roosevelt—"begum a new school of naval historical writing.

Other works by Mahan are a Life of Admiral Farragut (1892); The Interest of America in Sea Power (1897); Lessons of the War with Spain (1899); The Story of the War with South Africa and The Problem of Asia (1900); Types of Naval Officers drawn from the History of the British Navy (1901); Retrospect and Prospect, studies of international relations (1902).

MAHANADI, or Mundubuddi ("The Great River"), a river of India. It rises in 20° 10' N., 82° E., 25 m. S. of Raipur town, in the wild mountains of Bastar in the Central Provinces. At first an insignificant stream, taking a northerly direction, it drains the eastern portion of the Chhattisgarh plain, then a little above Seorinayana it receives the waters which its first great affluent, the Sonnath, has collected from the western portion of the plain; thence flowing for some distance due E., its stream is augmented by the drainage of the hills of Upora, Korba, and the ranges that separate Sambalpur from Chota Nagpur. At Padampur it turns towards the south, and struggling through masses of rock, flows past the town of Sambalpur to Sonpur. From Sonpur it pursues a tortuous course among ridges and rocky crags towards the range of the Eastern Ghats. This mountain line it pierces by a gorge about 40 m. in length, overlooked by forest-clad hills. Since the opening of the Bengal-Nagpur railway, the Mahanadi is little used for navigation. It pours down upon the Orissa delta at Naraj, about 7 m. west of Cuttack town; and after traversing Cuttack district from west to east, and throwing off numerous branches (the Katjori, Paika, Biropa, Chitaratala, Rees) falls into the Bay of Bengal at False Point by several channels.

The Mahanadi has an estimated drainage area of 43,800 sq. m., and its rapid flow renders its maximum discharge in time of flood second to that of no other river in India. During unusually high floods 1,500,000 cub. ft. of water pour every second through the Naraj gorge, one-half of which, uncontrolled by the elaborate
embankments, and heavily laden with silt, pours over the delta, filling the swamps, inundating the rice-fields, and converting the plains into a sea. In the dry weather the discharge of the Mahanadi dwindles to 1125 cub. ft. per second. Efforts have been made to husband what water there is by means of the vast water supply thrown upon the Orissa delta during seasons of flood. Each of the three branches into which the parent stream splits at the delta head is regulated by a weir. Of the four canals which form the Orissa irrigation system, two take off from the Mahanadi weir, and one, with its branch, from the Mahanadi weir. On the 31st of December 1868 the government took over the whole canal works from the East Indian Irrigation Company, at a cost of 591,568. The canals thus taken over and since completed, are the high-level canal, the Kendrapara canal, the Talindia canal and the Machgao canal, irrigating 37,000 acres.

**MAHANAYA** ("Great Vehicle"), the name given to the later Buddhism, the popular religion which embraced all the people and had its pantheon of Buddhas and Bodhisattvas, with attendant deities and demons, spacious temples and images, pompous ceremonial and noisy festivals. It was thus contrasted with the Hinayana ("Little Vehicle") of the primitive Buddhism which had been only for the select few. (See BUDDHISM.)

**MAHDI** (Arab. "he who is guided aright"), a title assumed by the third Abbasid caliph (see CALIPHATE: Abbasids, § 3). According to Moslem traditionists Mahomet declared that one of his descendants, the imam of God, who would fill the earth with equity and justice, would bear the name of al-mahdi. The Sunnis hold that this mahdi has not yet appeared. The name of mahdi is also given by the Shi'ite Mahomedans to the last of the imams of the house of 'Ali. It was under the name of al-mahdi that Mokhtar proclaimed 'Ali's son Mahammed as the opponent of the caliph Abdalmalik, and, according to Shahrastani, the doctrine of the mahdi, the hidden deliverer who is one day to appear and fill the oppressed world with righteousness, first arose in connexion with a belief that this Mahommed had not died but lived concealed at Mount Radwā, near Mecca, guarded by a lion and a panther. The hidden imam of the common Shi'ites is, however, the twelfth imam, Mahommed Abū'l-Qasim, who disappeared mysteriously in 799. The belief in the appearance of the mahdi readily lent itself to imposture. Of the many pretenders to this dignity known in all periods of Moslem history the most famous was the first caliph of the Fatimite dynasty in North Africa, 'Ahmad al-Mahdi, who reigned 906-933. After him was named the first capital of the dynasty, the once important city of Mahdia (q.v.). Another great historical movement, headed by a leader who proclaimed himself the mahdi (Mahommed ibn Abdallah ibn Tumart), was that of the Almohades (q.v.). In 1181 Mahommed Ahmed ibn Seyyid Abdullah (q.v.), a Dongolese, proclaimed himself al-mahdi and founded in the eastern Sudan the short-lived empire overthrown by an Anglo-Egyptian force at the battle of Omdurman in 1898. Concurrently with the claim of Mahommed Ahmed to be the mahdi the same title was claimed by, or for, the head of the Sunnites, a confraternity powerful in many regions of North Africa.

**MAHINDRA** (also spelt Mehdia, Mehedia, &c.), a town of Tunisia, on the coast between the gulfs of Hammamet and Gaces, 47 m. by rail S.S.E. of Susa. Pop. about 8000. Mahdia is built on a rocky peninsula which projects eastward about a mile beyond the normal coast line, and is not more than a quarter of a mile wide. The extremity of the peninsula is called Ras Mahdia or Cape Africa—Africa being the name by which Mahdia was designated by Froissart and other European historians during the middle ages and the Renaissance. In the centre of the peninsula and occupying its highest point is a citadel (16th century); another castle farther west is now used as a prison and is in the centre of the native town. The European quarter and the new port are on the south-west side of the peninsula. The port is available for small boats only; steamers anchor in the roadstead about a quarter of a mile from the shore. On the south-east, cut off from the rock, is the ancient harbour, or cothon, measuring about 480 ft. by 240 ft., the entrance being 42 ft. wide. There are manufactures of olive
MAHÉ—MAHMUD II.

oil, but the chief industry is sardine fishing, largely in the hands of Italians.

Mahdia occupies the site of a Phoenician settlement and by some authorities is identified with the town called Turris Hannibalis by the Romans. Hannibal is said to have embarked here on his exile from Carthage. After the Arab conquest of Libya, the town fell into decay. It was refounded in 912 by the first Fatimite caliph, 'Abdallah-al-Mahdi, after whom it was named. It became the port of Kairawan and was for centuries a city of considerable importance, largely owing to its great natural strength, and its position on the Mediterranean. It carried on an active trade with Egypt, Syria and Spain. The town was occupied by the Normans of Sicily in the 12th century, but after holding it for about twelve years they were driven out in 1159 by the Almohades. In 1390 a joint English and French force vainly besieged Mahdia for sixty-one days. In the early part of the 16th century the corsair Dragut seized the town and made it his capital, but in 1550 the place was captured by the Spaniards, who held it until 1574. Before evacuating the town the Spaniards dismantled the fortifications. Under the rule of the Turks and, later, the Bey's of Tunis Mahdia became a place of little importance. It was occupied by the French in 1851 without opposition, and regained some of its former commercial importance.

During 1908 numbers of bronzes and other works of art were recovered from a vessel wrecked off Mahdia in the 5th century A.D. (see Classical Review, June 1909).

MAHÉ, a French settlement in the Malabar district of Madras, India, situated in 11° 45' N. and 75° 33' E., at the mouth of a river of the same name. Area, 26 sq. m.; pop. (1901), 10,208. It is the only French possession on the west coast of India, and is in charge of a chef de service, subordinate to the governor-general at Pondicherry. It is now a decaying place.

MAHESHWAR, a town in Indore state, Central India, on the N. bank of the Narbada (Nerbudda). Pop. (1901), 7042. Though of great antiquity and also of religious sanctity, it is chiefly noted as the residence of Ahalya Bai, the reigning queen of the Holkar dynasty during the last half of the 18th century, whose ability and munificence are famous throughout India. Close by her cenotaph stands the family temple of the Holkars.

MAHI, a river of western India, which rises in Central India and, after flowing through south Rajputana, enters Gujarat and falls into the sea by a wide estuary near Cambay; total length, 300 m.; estimated drainage area, 16,000 sq. m. It has given its name to the Mahi Kantha agency of Bombay, and also to the mekwasit, marauding highlanders often mentioned in Mahomedan chronicles.

MAHI KANTHA, a political agency or collection of native states in India, within the Gujarath division of Bombay. Over half the territory is covered by the native state of Iidar. There are eleven other chiefships, and a large number of estates belonging to Rajput or Koli thakurs, formerly feudatories of Baroda. Several of the states are under British administration. Total area, 31,250 sq. m.; pop. (1901), 361,545, showing a decrease of 3.8% in the decade, due to famine; estimated revenue, £16,000; tribute (mostly to the gaekwar of Baroda), £9000. Many of the inhabitants belong to the wild tribes of Bhils and Kolis. In 1897 a metre-gauge railway was opened from Ahmedabad through Parantij to Ahmednagar. At Sadar is the Scott College for the education of the sons of chiefs on the lines of an English public school. There are also Anglo-vernacular schools at Sadar, Iidar and Mansa. The famine of 1899-1900 was severely felt in this tract.

MAHMUD I. (1690-1754), sultan of Turkey, was the son of Mustafa II., and succeeded his uncle Ahmed III. in 1730. After the suppression of a military revolt the war with Persia was continued with varying success, and terminated in 1736 by a treaty of peace restoring the status quo ante bellum. The next enemy whom Turkey was called upon to face was Russia, later joined by Austria. War went on for four years; the successes gained by Russia were outweighed by Austria's various reverses, terminating by the defeat of Wallis at Krotzka, and the peace concluded at Belgrade was a triumph for Turkish diplomacy. The sultan, throughout desires for peace, is said to have been much under the influence of the chief eunuch, Haji Bechir Aga. In 1754 Mahmud died of heart-disease, returning from the Frisian service at the mosque. He had a passion for building, to which are due numberless kiosques, where nocturnal orgies were carried on by him and his boon companions. In this reign the system of appointing Phaneroiots Greeks to the principalities of Moldavia and Wallachia was instituted. (See PHANEROIOTS.)

MAHMUD II. (1785-1839), sultan of Turkey, was the son of Abu-ul-Hamid I., and succeeded his brother, Mustafa IV., in 1808. He had shared the captivity of his ill-fated cousin, the ex-sultan, Selim III., whose efforts at reform had ended in his deposition by the janissaries. Mahmud was thus early impressed with the necessity for disarming his intention to institute reforms until he should be powerful enough to carry them through. The reforming efforts of the grand vizier Bairakdar, to whom he had owed his life and his accession, broke on the opposition of the janissaries; and Mahmud had no other resource but to flee the empire. For four years the empire seemed in danger of breaking up. Not till 1812 was the war with Russia closed by the treaty of Bucharest, which restored Moldavia and the greater part of Wallachia to the Ottoman government. But though the war was ended, the terms of the treaty left a number of burning questions, both internal and external, unsettled. This was notably the case with the claim of Russia to Poti and the valley of the Rion (Phasis), which was still outstanding at the time of the congress of Vienna (1814-1815) and prevented the question of a European guarantee of the integrity of Turkey from being considered.

Meanwhile, within the empire, ambitious valis were one by one attempting to carve out dominions for themselves at the expense of the central power. The ambitions of Mehemet Ali of Egypt were not yet fully revealed, but Ali (q.v.) of Jannina, who had marched to the aid of the sultan against the rebellious pasha Tamraz Oglu of Wildin, soon began to show his hand, and it needed the concentration of all the forces of the Turkish empire to effect his overthrow and death (1822). The preoccupation of the sultan with Ali gave their opportunity to the Greeks whose disaffection had long been organized in the great secret society of the Hetoria Philike, against which Metternich had in vain warned the Ottoman government. In 1821 occurred the abortive raid of Alexander Ypsilanti into the Danubian principalities, and in May of the same year the revolt of the Greeks of the Morea began the war of Greek Independence (see GREECE: History). The rising in the north was easily crushed; but in the south the Ottoman power was hampered by the defection of the sea-faring Greeks, by whom the Turkish navy had hitherto been manned. After three abortive campaigns Mahmud was compelled, infinitely against his will, to summon to his assistance the already too powerful army of Mehemet Ali. Mahmud employed all his power to suppress the rebellious Wabhabs in Arabia. The disciplined Egyptian army, supported by a well organized fleet, rapidly accomplished what the Turks had failed to do; and by 1826 the Greeks were practically subdued on land, and Ibrahim was preparing to turn his attention to the islands. But for the intervention of the powers and the battle of Navarino Mahmud's authority would have been restored in Greece. The news of Navarino betrayed Mahmud into one of those paroxysms of rage to which he was liable, and which on critical occasions were apt greatly to cloud his usual good sense. After vain attempting to obtain an apology for the unparalleled outrage against a friendly power he issued on the 20th of December a solemn hatti sherf summoning the faithful to a holy war. This, together with certain outstanding grievances and the pretext of enforcing the settlement of the Greek Question approved by the powers, gave Russia the excuse for declaring war against Turkey. After two hard-fought campaigns
Mahmud Nedim Pasha—Mahmud of Ghazni

(1828, 1829) Mahmud was at length, on the 14th of September 1829, compelled to sign the peace of Adrianople. From this moment until his death Mahmud was, to all intents and purposes, the "vassal of Russia," though not without occasional desperate efforts to break his chains. (For the political events of the period between the first revolt of Mehmet Ali (Sept. 1832) and the death of Mahmud see MEHMET ALI.) The personal attitude of the sultan, which alone concerns us here, was determined throughout by his overmastering hatred of the upstart pasha, of whom he had stooped to ask aid, and who now defied his will; and the importance of this attitude lies in the fact that, as the result of the success of his centralizing policy, and notably of the destruction of the janissaries (q.v.), the supreme authority, hitherto limited by the practical power of the ministers of the Porte and by the turbulence of the privileged military caste, had become concentrated in his own person. It was no longer the Porte that decided, but the Seraglio, and the sultan's private secretary had more influence on the policy of the Ottoman empire than the grand vizier.

This omnipotence of the sultan in deciding the policy of the government was in striking contrast with his impotence in enforcing his views on his subjects and in his relations with foreign powers. And, as a whole, despite of no small efforts and resources, was hated by his Mussulman subjects and stigmatized as an "infidel" and a traitor to Islam. He was, in fact, a victim to those "half-measures" which Machiavelli condemns as fatal to success. Ibrahim, the conqueror of Syria, scoffed at the sultan's idea "that reform consisted in putting his soldiers into tight trousers and epaulettes." The criticism is not entirely unjust. Mahmud's policy was the converse of that recommended by Machiavelli, viz. in making a revolution to change the substance while preserving the semblance of the old order. Metternich's advice to Mahmud to "remain a Turk" was sound enough. His failure to do so—in externals—left him isolated in his empire: raja and true believers alike distrusted and hated him. Of this hatred he was fully conscious; he knew that his subjects, even many of his own ministers, regarded Mehmet Ali as the champion of Islam against the "infidel sultan;" he suspected the pasha, already master of the sacred cities, of an intention to proclaim himself caliph in his stead. This, together with the unbroken refusal of the sultan to reform, drove him to rely on foreign aid; which, in the actual conditions of Europe, meant the aid of Russia. The long tradition of French friendship for Turkey had been broken, in 1830, by the conquest of Algiers. Austria was, for the time, but the faithful ally of the tsar. On the 9th of August 1832 Mahmud made, through Stratford Canning, a formal proposal for an alliance with Great Britain, which Palmerston refused to consider for fear of offending France. Mahmud bitterly contrasted the fair professions of England with the offers of effective help from Russia. His old ally having deserted him, he accepted the aid of his hereditary foe. The Russian expedition to the Bosporus, the convention of Kutahia, and the treaty of Unkari Skelessi (July 8, 1833) followed. Mahmud was under no illusion as to the position in which the latter placed him towards Russia; but his fear of Mehemet Ali and his desire to be revenged upon him outweighed all other considerations. He resented the action of France and England in forcing the settlement of Kutiah upon him, and remained shut up in his palace, inaccessible to all but his favorites and the representatives of Russia. With his single aim in view he busied himself with the creation of a national militia, with the aid of Moltke and other German officers. In 1834 the revolt of Syria against Ibrahim seemed to give him his opportunity. He pleaded the duty of a sultan to go to the aid of his subjects when oppressed by one of his servants; but the powers were obdurate, even Russia, much occupied in affairs nearer home, leaving him in the lurch. He was astute enough to take advantage of the offence given to the powers by Mehemet Ali's system of monopolies, and in 1838 signed with Great Britain, and afterwards with others, a commercial treaty which cut at the root of the pasha's system. A few months later his passionate impatience overcame his policy and his faith. The hand of death was upon him, and he felt that he must strike now or never. In vain the powers, now united in their views, warned him of the probable consequences of any aggressive action on his part. He would rather die, he exclaimed, or become the slave of Russia, than not destroy his rebellious vassal. On his sole initiative, without consulting his ministers or the council of the empire, he sent instructions to Haifiz Pasha, commanding the Ottoman troops concentrated at Bir on the Euphrates, to advance into Syria. The fatal outcome of the campaign that followed he did not live to hear. When the news of Ibrahim's overwhelming victory at Nessib (June 24, 1839) reached Constantinople, Mahmud lay dying and unconscious. Early in the morning of the 1st of July his proud and passionate spirit passed away.

Mahmud II. cannot be reckoned among the great sultans, neither had he any of the calculating statescraft which characterized Abd-ul-Hamid II.; but his qualities of mind and heart, none the less, raised him far above the mass of his predecessors and successors. He was well versed in state affairs and loyal to those who advised and served him, personally brave, humane and patriotic, more than a mere stageman and energetic, and always a man of his word. Unhappy, indeed, is the tenant of the immemorial corruption of Byzantium had fallen upon him too, and the avenue to his favour and to political power lay too often through unspeakable paths. In view of the vast difficulty of the task before him at his succession it is less surprising that he failed to carry out his ideas than that he accomplished so much. When he came to the throne the empire was breaking up from within; one by one he freed the provinces from the tyrannical rulers who, like Ali of Jannina, were carving out independent, or quasi-independent, empires within the empire. If he failed in his wider schemes of reform, this was only one more illustration of a truth of which other "enlightened" sovereigns besides himself had experienced the force, namely, that it is impossible to impose any system, however admirable, from above on a people whose deepest convictions and prejudices it offends.

There is a great deal of valuable material for the history of Mahmud and his policy in the unpublished F.O. records (1832-1839), volumes of correspondence marked Turkey.—From Sir Stratford Canning.—From Mr. Mandeville.—From Lord Ponsonby. Further works mentioned under Turkey: History; see MEHMET ALI.

W. A. P.

Mahmud Nedim Pasha (c. 1818-1883), Turkish statesman, was the son of Nejib Pasha, ex-governor-general of Bagdad. After occupying various subordinate posts at the Porte he became successively under-secretary of state for foreign affairs, governor-general of Syria and Smyrna, minister of commerce, and governor-general of Tripoli; minister successively of justice and of marine (1865); grand vizier from 1871 to 1872 and from 1875 to 1876. He was high in favour with Sultan Abd-ul-Aziz and fell much under the influence of General Ignatiev, the forceful Russian ambassador before the war of 1877-78, his subserviency to Russia earning for him the nickname of "Mahmudoff." His administration was most unsuccessful from every point of view, and he was largely responsible for the issue of the decree suspending the interest on the Turkish funds. He was minister of the interior from 1870 to 1883.

Mahmud of Ghazni (971-1030), son of Sabuktigin, Afghan conqueror, was born on the 2nd of October 971. His father had been allowed after his successful invasions, particular his numerous invasions of India. His military capacity was inherited from his father, Nasir-ud-din Sabuktigin, was strengthened by youthful experience in the field. Sabuktigin, a Turki slave of Alpachan, governor of Khurasan under Abdalmalik I. b. Nuh of the Samanid dynasty of Bokhara, early brought himself to notice (see Samanids). He was raised to high office in the state by Alpachan's successor, Abu Ishak, and in A.H. 366 (A.D. 977), by the choice of the nobles of Ghazni, he became their ruler. He soon began to make conquests in the neighbouring countries,

1 The name is strictly Mahmud.
and in these wars he was accompanied by his young son Mahmud. Before he had reached the age of fourteen he encountered in two expeditions under his father the Indian forces of Jaipal, raja of Lahore, whom Sabuktagin defeated on the Punjab frontier.

In 904 Mahmud was made governor of Khorasan, with the title of Saif ad-daula (ud-daula) (“Sword of the State”) by the Samanid Nuh II. Two years later, his father Sabuktagin died in the neighbourhood of Balkh, having declared his second son, Isma'il, who was then with him, to be his successor. As soon as Isma'il had assumed the sovereignty at Balkh, Mahmud, who was at Nishapur, addressed him in friendly terms, proposing a division of the territories held by their father at his death. Isma'il rejected the proposal, and was immediately attacked by Mahmud and defeated. Retreating to Ghazni, he there yielded, and was imprisoned, and Mahmud obtained undisputed power as sovereign of Khorasan and Ghazni (997).

The Ghaznevid dynasty is sometimes reckoned by native historians to commence with Sabuktagin’s conquest of Bost and Kedur (978). But Sabuktagin, throughout his reign at Ghazni, continued to acknowledge the Samanid suzerainty, as did Mahmud also, until the time, soon after succeeding to his father’s dominions, when he received from Qadir, caliph of Baghdad (see Caliphathe, C. § 25), a khilat (robe of honour), with a letter recognizing his sovereignty, and conferring on him the titles Yamin-oddaula (“Right hand of the State”), and Amin-ul-Millat (“Guardian of the Faith”). From this time it is the name of the caliph that is inscribed on Mahmud’s coins, together with his own new titles. Previously the name of the Samanid sovereign, Mansur II. b. Nuh is given alone with his own former title, Saif adulla Mahmud. The earliest of those of the new form gives his name Mahmud bin Sabuktagin. Thereafter his father’s name does not appear on his coins, but it is inscribed again on his tomb.

The new honours received from the caliph gave fresh impulse to Mahmud’s zeal on behalf of Islam, and he resolved on an annual expedition against the idolaters of India. He could not now carry out this intention, but a great part of his reign was occupied with his Indian campaigns. In 1000 he started on the first of these expeditions, but it does not appear that he went farther than the hill country near Peshawar. The hostile attitude of Khalaf ibn Ahmad, governor of Seistan, called Mahmud to that province for a short time. He was appeased by Khalaf’s speedy submission, together with the gift of a large sum of money, and further, it is said, by his subdued opponent addressing him as sulthan, a title new at that time, and by which Mahmud continued to be called, though he did not formally adopt it, or stamp it on his coins. Four years later Khalaf, incurring Mahmud’s displeasure again, was imprisoned, and his property confiscated.

Mahmud’s army first crossed the Indus in 1001, opposed by Jaipal, raja of Lahore. Jaipal was defeated, and Mahmud, after his return from this expedition, is said to have taken the distinctive appellation of Gha’ib (“Victory for the Faith”), but he is rarely so-called. On the next occasion (1002) Mahmud advanced, as far as Bhera on the Jhelum, when his adversary Anang-pol, son and successor of Jaipal, fled to Kashmir. The following year saw Mahmud at Multan. When he was in the Punjab at this time, he heard of the invasion of Khorasan by the Ilek Khan Nasir I. ruler of Transoxiana whose daughter Mahmud had married. After a rapid march back from India, Mahmud repelled the invaders. The Ilek Khan, having retreated across the Oxus, returned with reinforcements, and took up a position a few miles from Balkh, where he was significantly defeated by Mahmud.

Mahmud again entered the Punjab in 1008, this time for the express purpose of chastising Sëwâh Pâl, who, having become a Musulman, and been left by Mahmud in charge of Multan, had relapsed to Hinduism. The Indian campaign of 1009 was notable. Near the Indus Mahmud was opposed again by Anang-pol, supported by powerful rajahs from other parts of India. After a severe fight, Anang-pol’s elephants were so terror-struck by the fire-missiles flung amongst them by the invaders that they turned and fled, the whole army retreating in confusion and leaving Mahmud master of the field. Mahmud, after this victory, pushed on through the Punjab to Nagar-kot (Kanga), and carried off much spoil from the Hindu temples to enrich his treasury at Ghazni. In 1011 Mahmud, after a short campaign against the Afghans under Mahmimed ibn Sür in the hill country of Gur, marched again into the Punjab. The next time (1014) he advanced to Thânæsār, another noted stronghold of Hinduism, between the Sutlej and the Jumna. Having now found his way across all the Punjab rivers, he was induced on two subsequent occasions to go still farther. But first he designed an invasion of Kashmir (1015), which was not carried out, as his progress was checked at Lôh-kot, a strong hill fort in the north-west of the Punjab. Then before undertaking his longer inroad into Hindustan he had to march north into Khwârizm (Khiva) against his brother-in-law Mamûn, who had refused to acknowledge Mahmud’s supremacy. The result was as usual, and Mahmud, having committed Khwârizm to a new ruler, one of Mamûn’s chief officers, returned to his capital. Then in 1018, with a very large force, he proceeded to India again, extending his inroad this time to the great Hindu cities of Mathra on the Jumna and Kanauj on the Ganges. He reduced the one, received the submission of the other, and carried back great stores of plunder. Three years later he went into India again, marching over nearly the same ground, to the support, this time, of the raja of Kanauj, who, having made friendship with the Mamomedan invader on his last visit, had been attacked by the raja of Kalînjur. But Mahmud found he had not yet sufficiently subdued the idolaters nearer his own border, between Kabul and the Indus, and the campaign of 1022 was directed against them, and reached no farther than Peshawar. Another march into India the following year was made direct to Gwalior.

The next expedition (1025) is the most famous of all. The point to which it was directed was the temple of Somnath on the coast of the Gujurât peninsula. After an arduous journey by Multan, and through part of Rajputana, he reached Somnath, and met with a very vigorous but fruitless resistance on the part of the Hindus of Gujurât. Moslem feet soon trod the courts of the great temple. The chief object of worship it contained was broken up, and the fragments kept to be carried off to Ghazni. The story is often told of the hollow figure, cleft by Mahmud’s battle-axe, pouring out great store of costly jewels and gold. But the idol in this Sivite temple was only a tall block or pillar of hewn stone, of a familiar kind. The popular legend is a very natural one. Mahmud, it was well known, made Hindu temples yield up their most precious things. He was a determined idol-breaker. And the stone block in this temple was enriched with a crown of jewels, the gifts of wealthy worshipers. These data readily give the Somnath exploit its more dramatic form. For the more recent story of the Somnath gates see SOMNATI.

After the successes at Somnath, Mahmud remained some months in India before returning to Ghazni. Then in 1026 he crossed the Indus once more into the Punjab. His brilliant victory at the battle of Multan (1026) was repeated at Parsa, in the third year after this, his last, visit to India. The indignations of Mahmud and his father were almost, but not altogether, unvarying successes. The Moslem historians touch lightly on reverses. And, although the annals of Rajputana tell how Sabuktagin was defeated by one raja of Ajmere and Mahmud by his successor, the course of events which followed shows how little these and other reverses affected the invader’s progress. Mahmud’s failure at Ajmere, when the brave raja Bîsbal-deo obliged him to raise the siege but was himself slain, was when the Moslem army was on its way to Somnath. Yet Mahmud’s Indian conquests, striking and important in themselves, were, after all, in great measure barren, except to the Ghazni treasury. Mahmud retained no possessions in India under his own direct rule. But after the repeated defeats, by his father and himself, of two successive rajahs of Lahore, the conqueror assumed the right of nominating the governors of the Punjab as a dependency of Ghazni, a right which continued to be exercised by seven of his successors. And for a time, in the reign of Masmud II.
MAHOBA—MAHOMET

399

(1058-1114), Lahore was the place of residence of the Ghaznavid sovereign.

Mahomet, reigned at Ghazni in 1090, the year following his expedition to Persia. He is conspicuous for his military ardour, his ambition, strong will, perseverence, watchfulness and energy, combined with great courage and unbounded self-reliance. But his tastes were not exclusively military. His love of literature brought men of learning to Ghazni, and his acquaintance with Moslem theology, was recognized by the learned doctors.

The principal histories of Mahmud's reign are—Kiūsh-i-Yamīn (Utib); Tarikh-us-Subuktigin (Bailaki); Tabakat i Nasiri (Mihāj el-Sirāj); Razaut-us-Safa (Mir Khond); Habb-us-Sitar (Khondamir). See Elliot, History of India; Elphinstone, History of India. R. K. K. R. & R.'s translation of the Tarikh al-Sultan Mahomdi-I-Ghaznavi (1901).

MAHOBA, an ancient town in India, in Hamipur district of the United Provinces. Pop. (1901), 10,074. As the capital of the Chandel dynasty, which ruled over Bundelkhand from the 9th to the 13th century, the neighbourhood is covered with architectural antiquities, prominent among which are artificial lakes, formed by banking up valleys with masonry dams. The largest of these is more than 4 m. in circuit.

MAHOGANY, a dark-coloured wood largely used for household furniture, the product of a large tree indigenous to Central America and the West Indies. It was originally received from Jamaica; 521,300 ft. were exported from that island in 1753. It is known botanically as Swietenia Mahogani, and is a member of the order Meliaceae. It bears compound leaves, resembling those of the ash, and clusters of small flowers, with five sepal and petals and ten stamens which are united into a tube. The fruit is a pear-shaped woody capsule, and contains many winged seeds. The dark-coloured bark has been considered a feuillage, and the seeds were used by the ancient Aztecs with oil for a cosmetic, but the most valuable product is the timber, first noticed by the carpenter on board Sir Walter Raleigh's ship in 1595 for its great beauty, hardness and durability. Dr Gibbons brought it into notice as well adapted for furniture in the early part of the 18th century, and its use as a cabinet wood was first practically established by a cabinet-maker named Wollaston, who was employed by Gibbons to work up some mahogany brought to England by his brother. It was introduced into India in 1795, and is now cultivated in Bengal and as far north as Saraspur. The timber of species of Cedrela and Melia, other members of the order Meliaceae, are used as Mahogany, and the product of the West African Khaya senegalensis is known as African mahogany. There is some confusion between the product of these various trees and that of the Mahogany tree (The Timbers of Commerce, 1904) says: "The various species of mahogany and cedar are so confusing that it is difficult to make precise statements as to their structure or origin. I know of no convincing proof that any of the American kinds met with on the English market are the Mahogany of the West Indies, nor that those shipped from Africa are the wood of Khaya senegalensis. These two genera are very nearly allied to Cedrela and Melia, and it is difficult to separate any of the four from the rest by the characters of the wood. After giving the most careful attention to every detail, I lean to the view that if not all of the mahoganies commonly met with are Cedrellas."

Kigelia Dreggeana (natural order Bixiaceae), a native of South Africa, is known as Natal mahogany.

MAHOMET (strictly Muḥammad, commonly also Mohammed), founder of the religious system called in Europe after him Mahommedanism, and by himself Islam or Hinduism. He died, according to the ordinary synchronism, on the 7th of June 632 (12 Rabia, A.H. 11), and his birthday was exactly sixty-three or sixty-five years earlier, the latter number being evidently an interpolation in lunar years of a number involved in the Gregorian dates of solar years. The lunar year was introduced into Arabia by Mahomet himself quite at the close of his career; that which existed before was certainly solar. As it involved a process of intercalation—which, however, seems to have been arbitrary manipulated by priests, whence certain synchronisms cannot be got for the events in the Prophet's career. The number 63 for the years of his life may rest on tradition, though it is unlikely that such matters were accurately noted; it can also be accounted for by a priori combination. A Meccan, it is said, became a full citizen at the age of 63; this would be the age at which the mission might be started. The Medina period (of which count was kept) lasted ten to eleven years; for the Meccan period ten years would seem a likely length. Finally it was known that for some years—about three—the mission had been conducted secretly. The only event in contemporary history to which the Koran alludes in its earlier parts is the Persian conquest of Palestine in 616. Clearly Mahomet had begun to prophecy by that date.

Before the rise of Islam, Mahomet's native place, Mecca, appears to figure nowhere in historical records, unless there be a reference to it in the "valley of Bad" (Psalm lxxxiv. 6). Its sacred, and therefore archaic, name is Bakkah; hence the identification of the name with that of the sanctuary Makoraba, known to the Greek geographers, is not philologically tenable; although so eminent a linguist as Dozy evolved a theory of the origin of the city from this name, which appears to be South Arabian for "sanctuary," and has no connexion with Hebrew (as Dozy supposed). In the 3rd century of the Muslim chronology, the mythology of Mecca was collected and published in book form, but the minute and minute parts of the name and place, it is clear that there was no record of the mode in which the community inhabiting the place had got there, and that little was remembered with accuracy of the events which preceded the rise of its prophet. The city had a sanctuary, called the Cave (ka'ba), of which the nucleus was the "Black Stone," probably to be identified with Allah, the god of the community; both still exist, or rather their legitimate substitutes, as the Ka'ba has been repeatedly reconstructed, and the original Black Stone was stolen by the Carthaginians in the 4th century of Islam; they afterwards returned one, but it may or may not have been the same as that which they removed. At some time in the 6th century—said to have been the birth-year of the Prophet, but really much earlier—an Abyssinian invader raided Mecca with the view of abolishing this sanctuary; but for some reason had to desist. This expedition, known as the "Raid of the Elephant," one of these animals being employed in its work, seems to have been of great importance for explaining the rise of Islam; for a sanctuary which can repel an invader acquires tremendous reputation. Some verses in the Koran which are perhaps not genuine, record it. There is a famous saying of the "People of the Elephant." The sanctuary was apparently in the possession of the tribe Koreish (Quraish), the origin of whose name is unknown, said to have come originally from Cutha in Mesopotamia. They were known (we are told) as the people of Allah, and, by wearing a badge, were sacerosans throughout Arabia. If this be true, it was probably a privilege earned by the miraculous defence of the Ka'ba, and is sufficient to account for the rise of Meccan commerce of which we hear much in the biography of the Prophet, and to which some verses of the earliest part of the Koran allude; for merchants who were safe from raids by bandits would have an enormous advantage. The records seem, however, to be inconsistent with this assertion; and the growth of the Meccan commerce is sufficiently accounted for by the fact that after the Abyssinian invasion pilgrimage to the Ka'ba became the practice of numerous Arab tribes, and for four months in the year (selected by Meccan priests) raiding was forbidden, in order to enable the pilgrimage to be safely made. In addition to this it would seem that all Mecca counted as sanctuary—i.e. no blood might under any circumstances be shed there. The community lived by purveying to pilgrims and the carrying trade; and both these occupations led to the immigration of strangers. There seems to be no doubt that Mahomet was himself a member of the tribe Koreish, and in deed too many of his relatives figure in history to permit of his parentage being questioned. His cousin 'Ali, fourth caliph, was the son of Abu Ṭalib, whose name attests the historical character of the kindred name 'Abd al-Muṭṭalib, Mahomet's grandfather: for the fact that this name is in part etymological is certainly no argument against its genuineness. In the 3rd century of Islam
a document was shown in which a man of San'a in Yemen acknowledged that he had borrowed from 'Abd al-Muṭṭalib 1000 silver dirhems of the Hudaist standard, and Allāh with the two "angels" (probably a euphemism for the goddesses Al-lāt and al-'Uzza) served as witness; it is difficult to see why such a document should have been forged. The name Ḥashim (for 'Abd al-Muṭṭalib's father) may or may not be historical; here, as in the ascending line throughout, we have subjects without predicates. The name of 'Abd al-Muṭṭalib's son, who was Mahomet's father, is given as 'Abdallāh; the correctness of this has been questioned, because "Servant of Allāh" would seem to be too appropriate, and the name was often given by the Prophet to converts as a substitute for some pagun appellation. This, however, is hypercritical, as the name of the father could not easily be altered, when relatives abounded, and it would seem that at one time the Prophet made no theological use of the name Allāh, for which he intended to substitute Rasūlmān. The name of his mother is given as Āminah, and with this one of his own titles, Amin, agrees; although the Arabs do not appear to have fused the two into connexion. Her father's name is given as Wābb, and she is brought into relation with a Medine tribe called the Banū 'Adī b. al-Najjār, to whom she is said to have brought her son in his early infancy. The circumstances may have been suggested by his later connexion with that place; yet in what seems a historical narrative her grave is mentioned as known to be at Abwa, midway between the two cities, whence this early bond between the Prophet and his future home may have really existed.

His own name is given in the Koran in the forms Ahmad and the familiar Muḥammad; in contemporary poetry we also find the form Maḥmūd. Similar variation between derivatives from the same root is found in proper names which occur in early poetry; the meaning of all would be "the praised," if the root be given its Arabic signification—"the desired" if interpreted from the Hebrew.

The form Muḥammad (ordinarily transliterated Mohammed; Mahomet, Meteh, &c., represent the Turkish pronunciation) is found in a pre-Islamic inscription, and appears to have been fairly common in Arabia. In Ḥag. ii. 7 a derivative of the Hebrew equivalent root occurs in the prophecy, and the desire of all nations shall come," and this passage has suggested the idea that the name may have been taken by the Prophet as the equivalent of "Messiah," while the Moslems themselves find its equivalent in the Paraclete of the Fourth Gospel, though this identification requires more study. This reservoir, the Arab title of respect, in which a man is called after his son) is ABDUL-'OLAYM; other names by which he is called are titles of honour, e.g. Muṣṭafā "chosen." (See further the genealogical table, ad fin.)

In the Koran, Allāh says that He found the Prophet an orphan, poor and astray; it is possible that all these expressions should be understood figuratively, like the "poor, naked, blind" of Christian hymns; the Arabs, however, take them literally, and Mahomet is said to have been a posthumous child, whose mother died a few months or years after his birth, and whose name was brought up first by his grandfather, and then by his own Moṭṭalib, one of the poorer members of the family; in the controversy between the Alīd and Abbasid pretenders of the 2nd century of Islam the Abbasid Muḥṣir claims that his ancestor fed the ancestor of 'Ali, i.e. Abū Ṭālib, otherwise he would have had to beg. There was evidently an apparent inconsistency between Mahomet's being a poor orphan and the favourite grandchild of the eminent and wealthy 'Abd al-Muṭṭalib; and it was solved in this way. There was a tradition that in his early years he was sent into the desert to acquire the habits and the language of the Bedouins; and this seems to have been attested by the Prophet himself. In a tribal fight he is said to have acted as armoured-bearer to one of his uncles, Zubair. There seems no doubt that he often accompanied Meccan caravans to the countries with which the Meccans had trade relations; such especially were Syria and south Arabia, and perhaps Egypt and Mesopotamia. It is conceivable that he may have visited Abyssinia by sea. For though accurate knowledge is nowhere to be found in the Koran, it exhibits a large amount of miscellaneous information, such as a trader might well pick up.

His career as a caravan-conductor appears to have terminated with his marriage to Khadija, daughter of Khawalid, represented by the tradition as a wealthy widow, fifteen years his senior and forty years of age at the time of the union. As she became the mother of a numerous family, a special rule was discovered by Moslem physiologists extending the child-bearing period of Korashite women beyond that of others. Since it is claimed for Mahomet that he first gave Arab women the right to inherit property, the difficulty noticed is not the only one connected with this marriage; and Robertson Smith has called attention to some others, unconnected with his theory of "marriage and kinship in early Arabia." After his marriage Mahomet appears to have been partner in a shop in Mecca; where he apparently sold agricultural produce. His style is strongly marked by phrases and metaphors drawn from trade, though as a statesman he never displayed any financial ability.

Writing in the monumental script of South Arabia had been known for centuries in the peninsula; and shortly before the rise of Islam a cursive script—the parent of the ordinary Arabic character—had been started in the Christian state of Hira, with which the beginnings of modern Arabic literature are connected. A modification of this had been introduced into Mecca, and was probably used for contracts and similar documents. The word ummi, literally "populär" or "plebeian" (according to one etymology), applied to Mahomet in the Koran, is said to mean "one who cannot read nor write," and the most generally accepted view is that he could do neither, a supposition which enters into the doctrine of the miraculous nature of the Koran. According to another interpretation the word means "Meccan," i.e. native of "the Mother of the Villages" (Umm al-Qura); and the most probable theory is that he could do both, but unskilfully. Indeed on one historic occasion he erased certain words in a document; and where in the Koran he rebuts the charge of "taking notes," he does not employ the obvious retort that he could not write, but gives a far less convincing answer. For poetry, which seems to have been cultivated in Arabia long before his time, he possessed no ear; but we have little reason for supposing that either writing or versification had yet entered into Arabic education. The former would be acquired by those who needed it, the latter was regarded as a natural gift. There is reason for thinking the language of the Koran incorrect and ungrammatical in parts, but as it afterwards became the ultimate standard of classical Arabic, this point is not easy to prove. On the whole then his early life seems to have been such as was normal in the case of a man belonging to one of the more important families in a community which had not long been started on a career of prosperity.

Of the organization of that community we unfortunately know very little, though we hear of a council-chamber, and, as has been seen, of an age-qualification for admission to it. It is, however, certain that the theory of decision by majority was absolutely unknown to Mahomet's second successor, whence we learn little from this tradition (even if it be authentic) of the mode whereby the tribes who together formed the Meccan population managed their common concerns, whether commercial or political. The form of government seems to have been a rudimentary oligarchy, directed by some masterful individual; before the Flight we read of various prominent personages, after the Flight and the battle of Badr (A.H. 2) one chief-tain, 'Abū Sofiān (see CALIPHATE, ad init.), appears to take the lead whether in war or in policy. It would seem, however, that the right of independent action belonged to the individual tribes, even to the extent of refusing to take part in a campaign. For the settlement of ordinary disputes recourse was had (it appears) rather to soothsayers, near or distant, than to any regularly constituted authority or tribunal. On the other hand we are told a list of officials who were concerned with different parts of the festal performances and the ordinary worship. Of these we may mention the Custodian of the Ka'ba, and the official whose duty was siyāyah ("watering"), said to mean furnishing the pilgrims with water,
but more ingeniously interpreted in recent times as "rain-bringing," a function which even in the 1st century of Islam the governor in some places was supposed to exercise.

Of Arabian paganism we possess no trustworthy or complete account; since we hear of no theological literature belonging to it, probably no such account could have been given. There were doubtless a variety of practices, many of which have been continued to this day in the ceremonies of the pilgrimage, and offerings of different sorts to various deities, interpreted variously by the worshippers in accordance with their spiritual, intellectual and moral levels; e.g. as actual stones, or as men (or more often women) residing in the stones or otherwise connected with them, or bearing a similar relation to trees, or stars, &c. In general every tribe had its patron of the kind, and where there were aggregations of tribes, connexion were established between these deities, and affilition-theories exogotated; hence the theory attributed in the Koran to the Meccans that the goddesses al-Uzza, &c. were the daughters of Allah, may well represent the outcome of such speculation. These, however, were known to few, whereas the practices were familiar to all. Some of these were harmless, others barbarous; many offensive, but not very reprehensible, superstitions.

Before Mahomet's time Arabian paganism had already been attacked both from the outside and from the inside. On the one hand the northern tribes had gradually been christianized, owing to the influence of the Byzantine empire; on the other hand south Arabia had fallen successively under Jewish, Abyssinian and Persian influence; and the last, though little is known of Persian rule, is unlikely to have favoured pagan cults. Christianity had also some important representation in Najran far south of Mecca, while Jewish settlements were prospering north of Mecca in the Prophet's future home Yathrib and its neighbourhod. Power, civilization and learning were thus associated with monotheism (Judaism), dualism (Mazdaism) and tritheism (as the Arabs interpreted Christianity); paganism was the religion of ignorance (jahlityyah, interpreted by Goldziher as "barbarism," but the difference is not very considerable). Mecca itself and the neighbouring and allied Taif are said to have produced some monotheists or Christians, who identified the Allāh of Mecca with the Allāh of the Syrian Christians, called by the Abyssinian Christians "Lord of the Regions," and by the Jews "the Merciful" (Rahimān); one such is said to have been a cousin of Khdajja, Mahomet's wife; his name is given as Waraqah, son of Naufal, and he is credited with copying or translating a Gospel. We even hear of flagellant monks and perverts vowed to total abstinence among the precursors of Islam.

With these persons Mahomet had little in common, since they do not appear to have claimed to enforce their views upon others, or to have interfered with politics. He appears mainly to have been struck by the personality of the founders of the systems dominant in the civilized world, and to have aspired from the first to occupy the place of legislator or mouthpiece of the Deity; and that he was this was and is the main proposition of the Mahomedan creed. The "Prophet" or "Apostle" (at different times he employed both the Jewish and the Christian phrase) was the divinely appointed dictator of his community; if he were not obeyed, divine vengeance would overtake the disobedient. At this proposition Mahomet arrived by induction from the records of the Biblical prophets, as well as others who seem to have figured in Arabian mythology, e.g. the destruction of the tribe Thamud (mentioned by Pliny, and therefore historical) for their disobedience to their prophet Salih, and of 'Ad (probably mythical) for their similar treatment of Hud. The character of the message did not affect the necessity for obedience; at times it was condemnation of some moral offence, at others a trivial order. Divine vengeance overtook those who disobeyed either.

This is the theory of the prophetic office which pervaded the Koran, wherein the doctrine is formulated that every nation had its divine guide and that Mecca before Mahomet's time had none. This place, then, Mahomet felt a divine call to fill. But we are never likely to ascertain what first put the idea into his mind. The fables which his biographers tell on this subject are not worth repeating; his own system, in which he is brought into direct communication with the Deity, though at a later period the angel Gabriel appears to have acted as intermediary, naturally leaves no room for such speculations; and since his dispensation was thought to be absolutely new, and to make a tabula rasa of the pagan past, his first followers, having broken with that past, left no intelligible account of the state of affairs which preceded their master's call. Some generations therefore elapsed before that past was studied with any sort of sympathy, and details could not then be recovered, any more than they can now be supplied by conjecture.

So far as Mahomet may be said from the first to have formulated a definite notion of his work, we should probably be right in thinking it to be the restoration of the religion of Abraham, or (as the Koran calls him) Ibrahim. Though we have no reason for supposing the name of Abraham or Ishmael to have been known in Mecca generally before Mahomet's time, the Biblical etymology was not apparently questioned by those who were told of it, and there are stories, not necessarily apocryphal, of precursors of Mahomet going abroad in search of the "religion of Abraham." One feature of that system, associated in the Biblical thought with the name of Ishmael as well, was circumcision, which was actually observed by the Meccan tribes, though it would appear with technical differences from the Jewish method; the association of monotheism with it would seem reasonable enough, in view of Jewish traditions, such as Mahomet may have heard on his travels; why the doctrine of the future life should be coupled with it is less obvious. That the Meccan temple and its rites had been founded by these two patriarchs appears to have been deduced by Mahomet himself, but perhaps at a later stage of his career. That these rites, so far as they were idolatrous, were in flagrant defiance of the religion of Abraham must have struck any one who accepted the accounts of it which were current among Jews and Christians. The precursors, however, appear to have felt no call to reform their fellow-citizens; whereas it is evident that Mahomet regarded himself as charged with a message, which he was bound to deliver, and which his God would in some way render effective.

As it was obvious that the claim to be God's mouthpiece was to claim autocracy, Mahomet employed the utmost caution in his mode of asserting this claim; on the question of his sincerity there have been different opinions held, and it is not necessary to take any view on this matter. For three years his followers were a secret society; and this period appears to have been preceded by one of private preparation, the first revelation being received when the Prophet was in religious retirement—a ceremony called ta'khinnāth, of which the meaning is uncertain, but which can have no connexion with the Hebrew 'tchinuith ("supplications")—on Mount Hirā, near Mecca.

If the traditional dates assigned to the suras (chapters) of the Koran (q.v.) are correct, the earliest revelations took the form of pages or rolls which the Prophet was to read by the "grace of God," as Joseph Smith, the founder of the Mormon community, said of the power given him to read the "Egyptian" characters on the gold plates which he had found. The command to read is accompanied by the statement that "his most generous Lord had taught man by the pen (calamus) which he did not know." Waraqah, to whom the event is said to have been communicated by Khadija, called these communications "the Greater Law (nomos)." The Prophet was directed to communicate his mission at the first only to his nearest relatives. The utterances were from the first in a sort of rhyme, such as is said to have been employed for solemn matter in general, e.g. oracles or prayers. At an early period the production of a written communication was abandoned, oral communications, delivered by the Prophet in trance; their delivery was preceded by copious perspiration, for which the Prophet prepared (in accordance with instructions found in the Koran)
by wrapping himself in a blanket. Trusty followers were instructed to take these utterances down, but the phenomena which accompanied their delivery at least in one case suggested imputation to the scribe, who apostatized in consequence. It is extraordinary that there is no reason to suppose that any official record was ever kept of these revelations; the Prophet treated them somewhat as the Sibyl did her leaves. This carelessness is equally astounding whether the Prophet was sincere or insincere.

If the matter afterwards collected in the Koran be genuine, the early revelations must have been miscellaneous in content, magical, historical and homiletic. To some strange oaths are prefixed. Apparently the purpose to be compassed was to convince the audience of their miraculous origin. The formulation of doctrines belongs to a later period and that of jurisprudence to the latest of all. In that last period also, when Mahomet was despot of Medina, the Koran served as an official chronicle, well compared by Spengler to the leading articles on current events in a ministerial organ. Where the continuous paragraph is substituted for the ejaculation, the divine author apologizes for the style.

Certain doctrines and practices (e.g. washing of the person and the garments) must have been enjoined from the first, but our authorities scarcely give us any clear notion what they were. The doctrines to which the Prophet himself throughout assigned most value seem to have been the unity of God and the future life, or resurrection of the body. The former necessitated the abandonment of the idolatrous worship which formed part of the daily life of Mecca, and in which Mahomet and Khadija had been accustomed to take their part. Yet it seems to have been due to the initiative of the proselytes themselves rather than to the Prophet's orders that the Meccan worship was actually flouted by them; for the anacode which represents the Prophet and his young cousin attempting to pull down the images in or about the Ka'ba appears to be apocryphal. The first Moslem ceremonies would appear to have been the religious meetings for the purpose of bringing the delivery of revelations, of which after the Prophet's death the sermon (khutbah) took the place. After various provisional meeting-places, the house of one al-'Arqam on Mt. Safa was adopted for this purpose; and here proselytes were initiated.

The names which the new community received from its founder are both philological puzzles; for the natural sense of Growth of the Early Community (Muslim) appear to be "traitors," and to this a contemporary war-song of Mahomet's enemies alludes; while Hani' (especially applied in the Koran to Abraham) seems to be the Hebrew word for "hypocrite." The former is explained in the Koran to mean "one who hands over his face or person to God," and is said to have been invented by Abu; of the latter no explanation is given, but it seems to signify from the context "devotee." Since the divine name Ṭūrān was at one time favoured by Mahomet, and his excommunication by Maslama of the tribe Ḥanifa, who figures in politics at the end of Mahomet's career must have been a religious leader far earlier, it has been suggested that the names originally belonged to Maslama's community. The honour of having been Mahomet's first convert is claimed for three persons: his wife Khadija, his cousin Ali, who must have been a lad at the commencement of the mission, and Abū Bekr, son of Abū Quḥāfah, afterwards Mahomet's first successor. This last person became Mahomet's alter ego, and is usually known as the Ṣiddiq (Heb. word signifying "the saint," but to the Arabs meaning "faithful friend"). His loyalty from first to last was absolutely unwavering; he was selected to accompany Mahomet on the most critical occasion of his life, the Flight from Mecca; Mahomet is said to have declared that had he ever made a confidant of any one, that person would have been Abū Bekr; implying that there were things which were not confided even to him. The success of the Prophet's enterprise seems to have been very largely due to the part played by this adherent, who possessed a variety of attainments which he put at Mahomet's service; who when an intermediary was required was always ready to represent him, and who placed the commendation of the Prophet above every other consideration, private or public. The two appear to have regularly laid siege to those persons in Mecca whose adherence was desirable; and the ability which many of the earlier converts afterwards displayed, whether as statesmen or generals, is a remarkable testimony to their power of gauging men. It seems clear that the growth of wealth in Mecca had led to the accentuation of the difference between persons of different station, and that many were discontented with the oligarchy which governed the city. Converts could, therefore, be won without serious difficulty among the aliens and in general those who suffered under various disqualifications. Some members of the Jewish community seem also to have joined; and some relics of the Abyssinian expedition (i.e. descendants of the invaders). Among the most important converts of the Meccan period were Mahomet's uncle Ṣamza, afterwards for his valour called "the Lion of God"; Abū al-Ṭūrān (Abdar-raḥman) son of 'Aff', Othman, son of 'Affān, who married two of the Prophet's daughters successively, and was Mahomet's third successor; and, more important than any save Abū Bekr, Omar, son of al-Khattāb, a man of extraordinary force of character, to whom siege seems to have been laid with extraordinary skill. At some time he received the honourable title Fārdiq ("Deliverer"); he is represented as regularly favouring force, where Abū Bekr favoured gentle methods; unlike Abū Bekr, his loyalty was not always above suspicion. His adherence is ascribed to the period of publicity.

The secrecy which marked its early years was of the greatest value for the eventual success of the mission; for when Mahomet came forward publicly he was already the head of a band of united followers. His own family appear to have been either firm adherents, or violent enemies, or lukewarm and temporizing—this is the best which can be said for 'Abbās, eponymus of the Abbasid dynasty; or finally espoers of his cause, on family grounds, but not as converts. Temple and Mackenzie (adding accounts of Mahomet's first appearance as a public preacher, which are evidently comments on a text of the Koran, we have reason for supposing that his hand was forced by ardent followers, who many times in his career compelled him to advance. The austere rulers of the community perceived that the claim made by Mahomet was to be dictator or autocrat; and while this was naturally ridiculed by them, some appear to have been devoted adherents of the gods or goddesses whom he attacked. The absence of dated documents for the period between this open proclamation (which in any case commenced before 616) and the Flight to Medina in 622 renders the course of events somewhat conjectural, though certain details appear to be well established. Apparently there was a war of words, followed by a resort to diplomacy and then to force; and then a period in which Mahomet's attention was directed to foreign conquests, resulting in his being offered and accepting the dictatorship of Yathrib.

Of the war of words we have an imperfect record in the Meccan suras of the Koran, which occasionally state the objections urged by the opponents. In the course of the debate the theological position of both parties seems to have shifted, and the knowledge of both was probably increased in various ways. The miracle of the Koran, which at first consisted in its mode of production, was transformed into a marvel connected with its contents; first by Mahomet's claiming to tell historical narratives which had previously been unknown to him; afterwards by the assertion that the united efforts of mankind and Jinn would be unable to match the smallest passage of the Koran in sublimity. Probably the first of these claims could not be long maintained, though A. J. Davis, "the Seer of Poughkeepsie," in our own time brought a similar one in regard to his Principles of Nature. Indeed both parties evidently resorted to external aid. To those who undertook to name the man who dictated stories of the ancients to Mahomet day and night, he replied that the individual whom they had in mind was a foreigner, whereas the Koran was in pure Arabic. This was obviously a quibble, for it was scarcely asserted that he delivered the matter dictated to him without
alteration. The purity of the Arabic also appears to have been very questionable; for several expressions appear to be Ethiopic rather than Arabic, and the person whom the Meccans had in mind is likely to have been an Abyssinian Christian, since the Christian technicalities of the Koran are mainly derived from the Ethiopic Gospels and Acts. On one occasion when some questions suggested by learned foreigners had been propounded to the Prophet he required a fortnight's delay before the revelation which solved them came; the matter contained in his reply was certainly such as required research. His sources of information seem at all times to have been legendary rather than canonical; and the community which seemed to his opponents to agree best with his views was that of the Sabians or Mandaеans (q.z.).

It has been suggested that Mahomet first threatened the Meccans with temporal punishment, and only when this threat failed to take effect resorted to the terrors of the Day of Judgment and the terrors of Hell; it seems however a mistake to distinguish between the two. These threats provided the Prophet with his most powerful sermons. The boasts of incomparable eloquence which the Koran contains are evidence that his oratorical power was effective. In his sermons, Mahomet, borrowing the Arabic poets talk of their compositions somewhat in the same way. These discourses certainly led to occasional conversions, perhaps more frequently among women than men.

The diplomatic war seems to have been due to the Prophet's increasing success, which led to serious persecution of Mahomet's less influential followers, though, as has been seen, no blood could be shed in Mecca. Abū Ṭālib, moreover, prevented him from being exiled, though he probably had to endure many personal insults. Something however had to be done for the persecuted Moslems, and (perhaps at the suggestion of his Abyssinian helper) Mahomet endeavoured to find a refuge for them in the realm of Axum. Abyssinia was doubtless connected in every Meccan mind with the "Expedition of the Elephant"; and such an alliance secured by Mahomet was a menace to the existence of the Meccan community. A deportation was therefore sent by the Meccan leaders to demand extradition of the exiles; and as chief of this expedition the future conqueror of Egypt, 'Amr b. al-ʿĀṣ (see 'Amr Ibn EL-ʿĀṣ), first figures in history. To frustrate his efforts Mahomet sent his cousin Jāfar armed with an exposition of the Prophet's beliefs and doctrines afterwards embodied in the Koran as the Sura of Mary (No. XIX.; though with the addition of some anti-Christian matter). The original document contained an account of the Nativity of Christ with various miracles not known to either the canonical or even the apocryphal gospels which have been preserved, but which would be found edifying rather than unorthodox by a church one of whose most popular books is The Miracles of the Virgin Mary. To this there were added certain notices of Old Testament prophets. The Abyssinian king and his ecclesiastical advisers took the side of Mahomet and his followers, whom they appear to have regarded as persecuted Christians; and an attempt made probably by the astute 'Amr to embroil them with the Abyssinians on the difficult question of the Natures of Christ failed completely. There seems reason for thinking that the Abyssinian king contemplated bringing back the exiles by force, but was diverted from this purpose by frontier wars; meanwhile they were safely harboured, though they seem to have suffered from extreme poverty. The want of an Abyssinian chronicle for this period is a serious disadvantage for the study of Islamic origins. The sequel shows that regular correspondence went on between the exiles and those who remained in Mecca, whence the former were retained within the fold of Islam, with occasional though rare apostasies to Christianity.

Mahomet's diplomatic victory roused the Meccan leaders to fury, and they decided on the most vigorous measures to which they could rise; Abū Ṭālib, Mahomet's protector, and the clan which acknowledged him as sheikh, including the Prophet and his family, were blockaded in the quarter which they occupied; as in other sanctuaries, though blood might not be shed, a culprit might be starved to death. That this did not occur, though the siege appears to have lasted some months at least, was due to the weak good nature of the Meccans, but doubtless also to the fact that there were enlisted on Mahomet's side many of great physical strength and courage (as their subsequent careers proved), who could with impunity defy the Meccan embargo. After a time however the besieged found the situation intolerable, and any assistance which they might have expected from the king of Axum failed to come. The course adopted by Mahomet was retraction of those of his utterances which had most offended the Meccans, involving something like a return to paganism. A revelation came acknowledging the effectiveness of the Meccan goddesses as well as Allah, and the Meccans raised the siege. News of the reconciliation reached the Abyssinian exiles and they proceeded to return.

By the time they reached the Arabian coast the dispute had disappeared. The revelation was discovered to be a fabrication of the Devil, who, it appears, regularly interpolates in prophetic revelations; such at least is the apology preserved in the Koran, whence the fabricated verses have been expunged. Since our knowledge of this episode (regarded as the most disgraceful in the Prophet's career) is fragmentary, we can only guess that the Prophet's hand had once more been forced by the more earnest of his followers that any compromise with paganism was impossible. The exiles went back to Abyssinia; and about this time both Abū Ṭālib and Khaḍirā died, leaving the Prophet unprotected.

He fled to the neighbouring oasis of Ta'if, where wealthy Meccans had possessions, and where the goddess al-ʿUzza was worshipped with special zeal—where she is said still to exist in the form of a block of stone. He had but little success there in proselytizing, and indeed had to cease preaching; but he opened negotiations with various Meccan magnates for a promise of protection in case of his return. This was at last obtained with difficulty from one Moṭ'īm b. 'Adī. It would appear that his efforts were now confined to preaching to the strangers who assembled at or near Mecca for the ceremonies connected with the feasts. He received in consequence some invitations to come and expound his views away from Mecca, but had to wait some time before one came of a sort which he could wisely accept.

The situation which led to Mahomet's Flight (hijra, anglicized incorrectly joyra, q.v.) was singularly favourable to Mahomet's enterprise, and utilized by him with extraordinary caution and skill. At the palm plantation called Yathrib, afterwards known as al-Medīna, Medina, "the City" (i.e. of the Prophet), there were various tribes, the two most important, called Aus and Khazraj, being pagan, and engaged in an intertribal feud, while under their protection there were certain Jewish tribes, whose names have come down to us as Qainuqa, Nadīr and Qurāīn—impling that the Israelites, as might be expected, imitated the totem nomenclature of their neighbours. The memory of these Israelites is exclusively preserved by the Moslem records; the main stream of Jewish history flowed elsewhere. In the series of combats between the Aus and Khazraj the former had generally been worsted; the Jews, as usual, had avoided taking any active part in the fray. Finally, owing to an act of gross perfidy, they were compelled to fight in aid of the Aus; and in the so-called battle of Bu'āth (Furus) the Jews had won a victory, doubtless attributed to the God of the Jews. As it has been seen, the divine name employed by Mahomet (Rāḥmān) was one familiar to the Jews; and the Yathribites who visited Mecca at feast-time were naturally attracted by a professed representative of Rāḥmān. The first Yathribite converts appear to have been Khazrajites, and one As'ad, son of Zurarah, is the most prominent figure. Their idea may have been in the first place to secure the aid of the Israelitic Deity in their next battle with the Aus, and indeed the primary object of their visit to Mecca is said to have been to request assistance for their war. For this the plan was substituted of inviting the Prophet to come to Mecca as dictator, to heal the feud and restore order, a procedure to which Greek antiquity offers parallels. The new converts were told to carry on secret propaganda in Yathrib with this end in view. At the next feast
some of the rival faction embraced Islam. A trusty follower of Mahomet, Mus'ab b. Umar, who resembled Mahomet in personal appearance, was sent to Yathrib to assist in the work. The correspondence between this person and the Prophet would, if we possessed it, be of the greatest value for the study of Islamic antiquity. We first hear at this time of the conditions of Islam, i.e. a series of undertakings into which the convert entered: namely, to abstain from adultery, theft, intemperance and lying, and to obey Mahomet in iicitus et honestis. The wholesale conversion of Yathrib was determined by that of two chieftains, Usaid b. Huraijah and Sa'd b. Mu'adh, both Ausites. The example of these was quickly followed, and Iconoclasm became rife in the place. At the next Meccan feast a deputation of seventy Yathribites brought Mahomet a formal invitation, which he accepted, after imposing certain conditions. The interviews between Mahomet and the Yathribites are known as the 'Agabah (probably with reference to a text of the Koran). The attitude of the Jews towards the Prophet and his adherents appears to have been the protection and harbouring of the older prolesytes, whom Mahomet most wisely determined to send before to Yathrib, where, in the event of the Yathribite loyalty wavering, they could be counted on with certainty. The welcome given these refugees (muhājirūn), as they were from this time known in contradistinction to the helpers (ansār) or allies from Yathrib, is said to have been of the warmest; a Helper with two wives would hand one over to a wiseless Refugee. A yet more important condition which preceded the Flight was readiness to fight men of all colours in defence of the faith.

Although the transactions with the people of Yathrib had been carried on with profound secrecy, the nature of Mahomet's contract with his new adherents was somewhat divulged to the Meccan magnates, and the danger of allowing an imitable Pantheist to establish a high-road of their north-bound caravans flashed upon them. The rule which forbade bloodshed in the sacred city had at last to be suspended; but elaborate precautions were to be taken whereby every tribe (except Mahomet's own clan) should have their share in the guilt, which would thus be spread over the whole community fairly. When the committee appointed to perpetrate the crime reached Mahomet's house, they found that it was too late; Mahomet had already departed, leaving Ali in his bed.

The actual Flight from Mecca to Yathrib has naturally been a favourite subject for romance, and indeed appears to have been executed with the greatest cunning. Accompanied by Abū Bekr only, Mahomet took refuge in a cave of Mt. Thaur, in the opposite direction to that which he intended to take finally, and there remained for three days; provision had been made of every requisite, food, powerful camels, a trusty and competent guide. The effects of the Prophet's absence were to have been favourable to Yathrib, where there was already some sort of Moslem oratory, is given as 8 Rabi' I., of the year a.h. 1; the fact that he arrived there on the Jewish Day of Atonement gives us the date September 20, 622. The Meccans, who had employed professional trackers to hunt down the fugitives, proceeded to confiscate the houses and goods of Mahomet and of his followers who had fled.

The safe arrival of Mahomet at his destination marks the turning-point in his career, which now became one of almost unbroken success; his intellectual superiority over both friends and enemies enabling him to profit by defeat little less than by victory. His policy appears to have been to bind his followers to himself and them to each other by every possible tie; he instituted brotherhoods between the Refugees and Helpers, which were to count as relationships for legal purposes, and having himself no sons, he contracted numerous marriages partly with the same end in view: e.g. with the infant daughter of Abū Bekr, Ayasha ('A'ishah), whose ability he appears to have discerned; and the unamiable Ḥafṣa, daughter of Omar. Of his own daughters three were given to faithful allies, the one by whom his line is supposed to have been continued to our time, Fāṭima, was reserved for his cousin Ali. Owing to his efforts the alliance between the Refugees and Helpers resisted numerous attempts on the part of enemies to break it up, and only towards the end of the Prophet's life, when he appeared to favour Meccans unduly, do we hear of any bitterness between the two communities.

The population of Yathrib, or, as it may now be called, Medina, soon divided into three groups: Mahomet's united followers; the Jews; and a party known as the "Hypocrites," i.e. professing Moslems, who were lukewarm, or disaffected, among whom the most prominent is 'Abdallah b. Ubayy, a Khazrajite chieftain, who is said to have himself aspired to be despot of Yathrib, and who till nearly the end of Mahomet's career figures somewhat as a leader of the opposition; of his importance there is no question, but the reason for it and the mode whereby he made it felt are often obscure. It would seem that the pagans remaining in Yathrib speedily adopted Islam after the Prophet's arrival, whence we hear little of serious opposition on their part. Coming to the capacity of prophet of the Israelish God, Mahomet at first seems to have courted alliance with the Jews, and to have been ready to adopt their system with very slight modifications—similar to those which, according to his opinion, Jesus had come to introduce. The Jews met these advances by submitting him to examination in the intricacies of the Korah, and, finding him very poorly equipped, proceeded to denounce him as an impostor; one of his examiners is said to have even translated the Korah into Arabic with a view of convicting him of ignorance and imposture. They are further charged with exercising their magical arts on the Prophet and his followers, and to have succeeded thereby in producing barrenness among the Moslem women. Their conduct must not of course be judged by the statement of their enemies; it is however clear that Mahomet soon found that there was no possibility of compromising with them on religious questions, or of obtaining their loyal support; meanwhile he discovered among them a new career, the inhabitants of Yathrib, called the Meccan Moslems, and the Jews, and useless as warriors except against each other. He therefore resolved on their extermination. His ruthlessness in their case compared with his patience and forbearance in the case of the "Hypocrites" was consistent with his principle (always faithfully observed) that no inquiry was permissible into the motives of conversion, and with his division of mankind into the two antagonistic factions Believers and Unbelievers. The latter principle, as will be seen, was somewhat modified before the end of his life.

Mahomet's failure to effect a compromise with the Jews caused a reaction in his mind towards peganism, and after about a year's residence at Medina the direction of prayer, which had till then been towards Jerusalem, was turned southward to the pagan temple at Mecca. With this change we may perhaps couple the adoption of the name Allah for the Arab, to the Moslem norm of "In the Name of Allah the Raḥmān the Merciful." The translation attached to the word Raḥmān, and the prefixing to it of the name Allah furnish clear evidence of theological transition, though the stages are not recorded; we know, however, that the Meccans approved of the name Allah, but objected to the name Raḥmān. Prayer (ṣalāt), said to have been prescribed on the occasion of the Prophet's ascent into heaven after a miraculous journey from Mecca to Jerusalem, began to assume a stereotyped form in the place of assembly built by Mahomet immediately after his arrival; the attitudes of prayer in use among many communities (e.g. the Jewish standing, the prostration of some Christian sects) were combined. In general it was Mahomet's principle, while taking over a practice from some other sect, to modify it so as to render the Moslem method absolutely distinct; thus when a summons to prayer became requisite, a new mode (by the voice of a crier called muwādhin or muṣāfin) preferred to the Christian hammer, a new sacred day was adopted, in lieu of the Jewish Saturday and the Christian Sunday, in the weekday on which he had safely reached Kuba, Friday; but the sanctity was reduced to the actual time occupied by public worship. On the subject of food he was satisfied with the regulations of the Council of
Jerusalem, recorded in Acts xv.; which were observed by few if any Christian sects. The prohibition of wine, which was enacted in A.H. 1, is said to have been occasioned by the notorious conduct of one of his followers when under the influence of liquor; Palgrave saw in it (perhaps with justice) a deliberate attempt to prevent harmony between Moslems and Christians, in whose most sacred rite wine is used. The Fast of Ramadān, in which food both liquid and solid is forbidden from sunrise to sunset, is said to be a pagan or semi-pagan institution; its importance for military training and discipline is not likely to have been overlooked by the Prophet. When the direction of prayer was altered, it is probable that Mahomet already intended to introduce into his system the whole of the pagan pilgrimage with its antique ceremonial (with, of course, a new interpretation); before this he is supposed to have aimed at the abolition of the Ka‘ba and all that appertained to it.

The difference between religious and civil law has never been recognized by Islamic jurists, whose manuals deal equally with the law of contract and the amount of the body to be washed before prayer; the Prophet’s ordinances on both subjects were suggested by the exigencies of each case, and not by any rigid dynamism of fixed advisers which was early heard before a revelation was issued. Even when this had been done the ordinance might be cancelled by an abrogating revelation; it being “easy for Allah” to substitute for a text already revealed another that was better or at least as good.

As Islam began to spread outside the limits of Medina both conversion to Islam and persistence therein were reduced to simple tests; the pronunciation of the double formula of belief in Allah and Mahomet was sufficient to indicate conversion, whilst payment of an income-tax, called by the Jewish names for alms (ṣaka‘ī and ṣadaqah), was evidence of loyalty. This income-tax, of which the definite assessment perhaps belongs to a later period, was for the support of necessitous converts—an element in the community whose presence accounts for the mode in which the development of the Islamic state proceeded.

The industries in which the Meccan Refugees had been engaged were not of a sort which they could exercise at Medina, where the palm took the place of the camel as the basis of society. Moreover the Prophet seems to have given some disastrous advice on the subject of palmiculture, and thereby to have accentuated the poverty of the place. He had, therefore, to find some fresh source of revenue in order to deal with this difficulty, and one of the Helpers is said to have suggested the plan which he adopted, viz. of attacking the Meccan caravans. With this view he organized a series of expeditions, taking the lead himself sometimes, while at others he gave it to one of his veteran followers; and at first only Refugees took part in them. The leaders of the caravans, however, were expert in evading attacks of this sort, which were doubtless regularly attempted by the desert tribes; and in the first year of his despotism Mahomet did not score a single success of the kind intended. The attempts were not wholly fruitless; for while on the one hand he accustomed his followers to campaigning, on the other he made a series of agreements with the chieftains of the tribes through whose territory the caravans ordinarily passed. Finding this course torture intolerable, he resolved to take advantage of his power to bind and to loose by sending an expedition of seven men under his cousin ‘Abdallāh b. Jahl to attack a caravan at the beginning of the sacred month Rajah, when, as raiding during such a season was unknown, success was practically certain. The commander on this, the Nakhlah raid, was given sealed orders, to be opened after two days’ march; the men were then to be given the option of retiring, if they disapproved. Of this no one seems definitely to have availed himself, and the raid ended successfully, for considerable booty was captured, while of the four persons who escorted the caravan two were made prisoners, one escaped, and one, ‘Amr b. Ḥaḍrami, was killed; he was the first person slain fighting against an Islamic force. The violation of the sacred month seems to have caused considerable scandal in Arabia, but led to no serious consequence; on the other hand the shedding of blood created a feud between the people of Mecca and the Refugees, with whom the Meccans long declined to identify the people of Medina. The fact that the man who had been killed was a client, not a citizen, made no difference. The circumstance that booty had been actually acquired appears to have helped the Prophet’s cause very considerably.

Both these consequences, the Meccan desire to avenge the blood that had been shed and the anxiety of the Medinese to take part in a successful raid, manifested themselves a few months later, when an expedition was organized by Mahomet on Meccan caravans, which had escaped him the previous year. Many desired to take part in the raid, and finally some 300 persons were selected, including a large number of “Helpers.” The leader of the caravan learned somehow that an attack was being organized by Mahomet on a large scale, and went to Mecca for aid, while hurrying home by forced marches. This is the first historical appearance of Abū Sofān (the leader of the caravan), who now for some years played the part of president in the Meccan opposition to Mahomet, and whose son was destined to found the second Mahomedan dynasty (see Caliphate, B). The day before the battle to be fought at Badr, near the point where the northern road leaves the coast to turn eastwards to Mecca, the Moslem army learned that the Meccan succour (some 1000 strong) was near, but that the caravan had escaped. The Meccans, it is asserted, would have returned home now that their object was secured, but the patrons of the man who had been killed in the former raid were compelled to strike for vengeance.

The battle (Ramadān 19, A.H. 2, usually made to synchronize with March 17, 624) ended in a complete victory for Mahomet, whose followers killed seventy of the enemy and took seventy prisoners—if we may trust what seem to be round numbers; it was attributed by him to divine co-operation, taking the form of an illusion wrought on the enemy, and the despatch of a regiment of angels to the assistance of the Believers, while on the other hand the treachery of the Devil did mischief to the Meccans.

The popular tradition attributed it to the prowess of some of Mahomet’s followers, especially his uncle ʿAbdallāh b. Ṣamā‘ and his cousin ʿAbdallāh b. ʿAmr, who in the narratives which have come down and which seem to be authentic the result is amply accounted for by the excellence of the Moslem discipline and the complete absence of any on the Meccan side. Mahomet himself is said to have fainted at the first sight of blood, and to have remained during the battle in a hut built for him to which swift camels were tied, to be used in case of a defeat; yet these accounts make him responsible for the tactics, whilst assigning the credit for the strategy to one Ḥobab b. al-Mondhir. Several of Mahomet’s old enemies and friends of Meccan days perished on this occasion; notably one Abū Jahl, his uncle, but represented as an implacable enemy; another hostile uncle, Abū Lahab, who is cursed in the Koran, was not present but died shortly after the battle.

The day is called in the Koran by a Syriac expression the “Day of Deliverance,” and both for internal and external politics it was of incalculable advantage to Islam. The booty and the ransoms of the prisoners provided the means for dealing with distress; the story of supernatural aid soothed the feelings of the defeated Meccans and had a tendency to divide them where else; whilst Mahomet in the popularity acquired by his victory was able to strike forcibly at his enemies in Medina. One of the sequels to the victory was a series of assassinations whereby critics of his actions were removed.

The defeat at Badr naturally led to efforts on the part of the Meccans to avenge their dead and besides to secure the commerce, by which they lived, from an enemy who was gradually getting all the seaboard that lay between Jeddah and Yanbo within his sphere of influence; and the year after Badr (A.H. 3) Abū Sofān was led to advise a force of 3000 men, against Medina itself; part of it was under Khālid b. al-Walid, one of the greatest of Arab captains, afterwards conqueror of Syria. It is said that Mahomet’s plan was to remain in Medina itself, and leave it to the
Meccan commander to discover some way of taking the place; 
but that his hand was forced by his more ardent followers. 
Others, however, assign this advice to Abdullah b. Ubayy, and 
make 'the Anab' the name given to the campaign in 
consequence fought under Mt Uhud (or Ohod), north-west of 
Medina, wherein Khalid succeeded in inflicting a severe defeat 
on Mahomet's forces; his uncle Hamza, hero of Badr, was 
killed on this occasion. Fortunately for the Moslems, the Meccans 
considered that they had finished their task when they 
discovered that they had killed a number of the former equal to those 
who had fallen at Badr on their own side; instead therefore of pursuing 
their victory they went home. The immediate effect on Arabia 
appears to have been to dissipate the illusion that the Prophet 
could count on supernatural assistance in his wars; and we hear 
of some blows being dealt him from outside. Meanwhile his 
relations towards the Medinese Jews had grown more and more hostile, 
and these are credited with doing their best to rouse the Meccans 
to a sense of the danger which threatened them in the continuance 
of the Prophet's power, and in general to stir up hostility 
against him in Arabia. Whether this part was played by them 
or not, in the fifth year of the Prophet's stay at Medina a fresh 
invasion of the territory took place by a vast confederate force 
of Meccans with their allies, the tribes Fazarah, Asad, Murrah, 
&c., to the number, it is said, of 10,000. This time the intention 
of the leaders was undoubtedly to stamp out Islam. For the 
first time in Arab warfare Mahomet resorted to the expedient 
of defending his city by a trench, called by a Latin name, and 
supposedly by a Persian convert. But he also employed agents 
to sow dissension among the confederates, and succeeded with 
this no less than with the other expedient. After a brief stay, 
and scarcely striking a blow, the confederacy dispersed, leaving 
the Jews who still remained in Medina to the summary vengeance 
of the Prophet. The want of records written from the Meccan 
standpoint renders the abortiveness of this last attempt at 
storming the Prophet's stronghold scarcely intelligible.

From this time, however, the road towards the eventual taking 
of Mecca became easy, and we are told that such was the 
importance attached to that city throughout Arabia that its acquisition 
meant for the Prophet the acquisition of the whole peninsula. 
The next year (A.H. 6) he deemed it advisable to make a truce 
with the Meccans (the Truce of Hodaibiyah), whereby he secured 
for his followers the right of performing the pilgrimage in the 
following year; on this occasion he even consented to forgo his 
title "Prophet of Allah," when the Meccans refused to sign a 
deed in which it was employed, greatly to the scandal of his more 
earnest followers, including Omar; they were however too deeply 
committed to Islam to be able to defy the Prophet. When the 
pilgrimage was performed (A.H. 7), Mahomet not only won 
important converts in the persons of Khalid and the no less 
able 'Amr b. al-'As, but in general impressed the population 
with the idea that his was the winning side. An excuse was easily 
found for invading Mecca itself in the following year, when Abu 
Sofan took the opportunity of embracing Islam before it was too 
late. Very little resistance was now made by the Meccans, 
whose chiefs were already in Mahomet's camp, and Mahomet 
used his victory with great moderation; his proscription list 
was finally reduced to two. The theory that all offences 
were cancelled by conversion was loyally observed. Moreover the 
Prophet incurred the displeasure of his Medinese friends by the 
avers who displayed to soothe the feelings of his former 
enslaved and antagonists. The Medinese, however, prevailed 
upon him to maintain his city as his political capital, 
while making Mecca the religious centre of his system; and 
this arrangement accounts perhaps more than anything else 
for the persistence of the system amid so many dynastic 
changes.

In the main he appears to have introduced little alteration 
into the government of Mecca, and it is said that he even declined 
to retaliate on those who had confiscated the possessions of the 
Refugees. Even the Ka'ba was left in the keeping of its former 
custodian, though of course its interior as well as its precincts 
were cleansed of all that could offend monotheists. In the 
following year the pilgrimage was for the first time conducted 
by a Moslem official, Abu Bekr. A proclamation was made on that 
occasion, forbidding idolaters in future to take part in the 
pilgrimage, as well as the Moslems who had not as yet converted 
four months' grace before was to be brought to bear upon 
them. In the following year Mahomet conducted the Pilgrimage 
himself. This solemn occasion (the "Pilgrim's Farewell") 
was also employed for the delivery of an important proclamation, 
wherein the Prophet declared that God had completed their 
religion. The principle whereon he specially insisted was the 
brotherhood of Islam; but there is some difficulty in elucidating 
the original sermon from later additions.

It would seem that Mahomet's enterprise originally comprised 
the conversion of Mecca only, and that he thought of himself 
as sent to his fellow-citizens only, as had been the 
case with earlier prophets, whose message was for 
their "brethren." His views took a somewhat 
different direction after his brief exile to Taif, and the conquest 
of Arabia was in a way forced upon him in the course of his 
struggle with the Meccans. It is not indeed perfectly clear by 
what process he arrived at the resolution to exclude paganism 
from Arabia; at first he appears to have tolerated it at Medina, 
and in some of his earlier contracts with neighbouring tribes he 
is represented as allowing it, though some of our texts make him 
reserve to himself the right of enforcing Islam if he chose; 
only the Meccans were at first, according to the most authentic 
texts, proscribed; but this was much softened from all truce or treaty. At the battle of 
Badr he appears to have formulated the rule that no one might 
fight on his side who had not embraced Islam; and when once 
he had won fame as a successful campaigner, those who wished 
to share his adventures had to pass the Islamic test. After the 
battle of Uhud (Ohod) we hear of a tribe demanding missionaries 
to instruct them in Islamic principles; and though in the case 
recorded the demand was treacherous, the idea of sending 
missionaries appears not to have been unfamiliar even then, 
though the number sent (70), if rightly recorded, implies that the Prophet 
suspected the good faith of the applicants. After the taking 
of Mecca, whereby the chief sanctuary at any rate of north Arabia 
was cleared of all idolatrous associations, and consecrated 
unto monotheism in general was conscious of being 
attacked; and the city had scarcely been brought under the 
new régime before the Prophet had to face a confederation of 
tribes called Hawazin and Thaqif. The battle which ensued, 
known as the Day of Honain, was near ending disastrously 
for Islam; some of Mahomet's stoutest followers fled; but the 
terrible danger of a defeat in the neighbourhood of recently 
conquered Mecca roused the Prophet and Ali to heroism, and they 
saved the day. Emissaries were now sent far and wide 
demanding the destruction of idols, and only Taif appears to have 
made any tolerable resistance; against this place for the first time 
the Prophet made use of siege artillery, such as was employed by 
the Byzantines; though compelled by the bravery of the inhabi-
tants to raise the siege, he was afterwards able to take the city 
by capitulation. It has been observed that here only do we 
read of much attachment to the old deities; in most places they 
were discarded with few regrets when once their impotence had 
been found out. After the taking of Mecca and the victory 
of Honain there appears to have been a general desire, extending 
even to the extreme south of Arabia, to make the best terms with 
the conqueror so soon as possible; iconoclasticism became general. 
Flatterers of various kinds, including poets, came to seek the 
favour of the sovereign; and a mock war of words appears 
to have been substituted by some tribes for more serious 
fighting, to terminate in surrender. For warfare of his sort Mahomet 
had a powerful helper in the poet Hassan b. Thabit, for whose 
inspirational ideas a pulpit was erected in the Medina mosque, and whose 
verses were said to be inspired by the Holy Spirit; though, as 
has been seen, Mahomet was not himself able to judge of their 
artistic merit. It was not, however, found easy to enforce the 
payment of the alms on these new converts; and this taxation 
caused an almost general revolt so soon as Mahomet's death had 
been ascertained.
Although the central portions of the peninsula in Mahomet’s time were practically independent, large portions of the northeast and south-east were provinces of the Byzantine and Persian empires respectively, whence any scheme for the conquest of Arabia would necessarily involve the conqueror in war with these great powers. The conquest of Persia is said to have been contemplated by the Prophet as early as A.H. 5, when the famous Trench was being dug; but it was not till the year A.H. 7, on the eve of the taking of Mecca, that the Prophet conceived the idea of sending missives to all known sovereigns and potentates, promising them safety, if, but only if, they embraced Islam. The text of these letters, which only in the name of the person addressed, is preserved (doubtless unfairly) by the Moslem Oral Tradition; in the middle of the last century a French explorer professed to discover in Egypt the original of one of them—addressed to the mysterious personage called the Muqauqis (Μουκαουης) of Egypt—and this, it appears, is still preserved amid other supposed relics of the Prophet in Constantinople, though there is little reason for believing it to be genuine. The anecdotes dealing with the reception of these letters by Muhammad’s friends and admirers in high places in the empire appear to have sent favourable replies: the king of Axum, who now could send the exiles whom he had so long harboured to their successful master; and the Egyptian governor, who sent Mahomet a valuable present, including two Coptic women for his harem. The emperor Heraclius is claimed as a secret convert to Islam, on whom pressure had to be put by his advisers to conceal his convictions. The Persian king is said to have sent orders to have Mahomet arrested; his messengers arrived in Medina, but were unable to carry out the commands of their master, who died while they were there. Two of the letters are said to have had important results. One was addressed to the Himyarite chiefs (called by the south Arabian appellation gail) in Yemen, and effected their conversion; another to the governor of Bostra in Roman Arabia, who put the bearer of this insolent message to death; a force was despatched by Mahomet immediately afterwards (beginning of A.H. 8) to avenge this outrage; and though the Moslems were defeated in their first encounter with the Byzantine forces at Mutmah, they appear to have given a good account of themselves; it was here that Jaffar, cousin of the Prophet, met his death. In A.H. 9 a successful expedition was led by the Prophet himself northward, in which, though no Byzantine force was encountered, a considerable region was withdrawn from the Byzantine sphere of influence, and made either Islamic or tributary to Islam. At the time of his death (of fever, after a short illness) he was organizing an expedition for the conquest of Syria.

The Prophet claimed throughout that his revelation confirmed the Jewish and Christian Scriptures, and this claim is on the whole reasonable, though his acquaintance with both was in the highest degree vague and inaccurate. Still he reproduced the Old Testament as faithfully as he could, and though he patriotically endeavours to shed some lustre on his supposed ancestor Ishmael, he does not appear to have questioned the Biblical theory according to which the founder of the north Arabian nations was the son of a slave girl. On neither the truth of the Biblical history and miracles nor the validity of the Mosaic legislation does he appear to have cast any doubt. He even allows that Israel was the chosen people. The Gospel was known to him chiefly through apocryphal and heretical sources, which cannot certainly be identified; but he accepted the doctrine of the Virgin-birth, the miracles of healing the sick and raising the dead, and the ascension; the crucifixion and resurrection were clearly denied by the sect from whom he had received his information, and rejected by him, though certainly not because of any miracle which the latter involved. His quarrel with the Jews at Medina appears to have been by no means of his own seeking, but to have arisen unavoidably, owing to his particular view of his office being such as they could not accept; and his attempt to discredit, not the Mosaic Law, but the form in which they presented it, was an expedient to which he resorted in self-defence. An attempt was made shortly after his arrival at Medina to settle the relations between the two communities by a treaty, according to which, while their equality was guaranteed there should be little interference between the two; this, however, was found unworkable, and each victory of Mahomet over the Meccans was followed by violent measures against the Medinese Israelites. When experience had shown him their military incompetence he appears to have been unable to resist the temptation to appropriate their goods for the benefit of his followers; and his attack on the flourishing Jewish settlement of Khairabar, after the affair of Ḥodaiibiyah, appears to have been practically unprompted, and designed to satisfy his discontented adherents by an accession of plunder. Yet the consciousness that this process was economically wasteful suggested to him an idea which Islamic states are only now abandoning, viz. that of a tolerated caste, who should till the soil and provide sustenance for the Believers who were to be the fighting caste. Whereas then his former plan in dealing with Israelites had been to banish or massacre, he now left the former owners of Khaibar (who had survived the capture of the place) in possession of the soil, of whose produce they were to pay a fixed proportion to their conqueror, who was adopted in the case of later conquests of Jewish settlements.

Disputes with Christians occur somewhat later in the Prophet’s career than those with Jews, for neither at Mecca nor Medina were the former to be found in any numbers; individuals are likely to have been found in both cities, and we hear of one Medinese “Abu’Amir the Monk,” who after Mahomet’s arrival at Medina branded him as an impostor, and, going himself into exile, made many an abortive attempt to discredit and injure Mahomet’s cause. The notices of him are meagre and obscure. Mahomet’s manifesto to the world, about the time of the taking of Khairabar, appears to represent his definite breach with Christianity; and when in the “year of the embassies” the Christians of Najran sent a deputation to him, they found that the breach between the two systems was not to be healed. Of the three alternatives open to them—conversion, internecine war, and tribute, they chose the last. The Christian tribes of north Arabia showed greater inclination towards the first. The Prophet’s policy was to give Christians lighter terms than Jews, and though the Koran reflects the gradual adoption by the Prophet of an attitude of extreme hostility to both systems, its tone is that of the whole far more friendly to the former than to the latter. Some other communities are mentioned in the Koran, but merely in casual allusions: thus we know that Mahomet’s sympathy was with the Byzantines in their struggle with Persia, but in his most tolerant utterance the Magians or Mazdians as well as the Sabians (with whom his followers were identified by the Meccans) are mentioned with respect.

The financial requirements of Mahomet’s state were of the simplest kind, for there is no trace of any form of governmental department having been instituted by him, even when he was master of the peninsula; nor can we name any permanent officials in his employ except his muaddhin Bilal, and perhaps his court-poet Ḥassan. A staff of scribes was finally required both to take down his revelations and to conduct correspondence; but although he encouraged the acquisition of penmanship (indeed some of the prisoners at Badr are said to have been allowed to ransom themselves by teaching it to the Medinese), we know of no regular secretaries in his employ. After the death of Mahomet he combined the functions of legislator, administrator, general and judge: his duties in the last three capacities were occasionally delegated to others, as when he appointed a governor of Medina during his absence, or leaders for expeditions, with provision for successors in case of their falling, but we hear of no permanent or regular delegation of them. Till near the end of his career at Medina he maintained the principle that migration to that city was a condition of conversion; but when, owing to the extension of his power, this was no longer practicable, his plan was in the main to leave the newly converted communities to manage their internal affairs as before, only sending occasional envoys to discharge special duties, especially instruction in the Koran and
the principles of Islam, and to collect the Alms; quite towards the end of his life it appears to have sent persons to the provinces to act as judges, with instructions to judge according to the Koran, and where that failed, the practice (sunna), i.e. the practice of the community, for which a later generation substituted the practice of the Prophet. There were, therefore, no regular payments to permanent officials; and the taxation called Alms, which developed into an income-tax, but was at first a demand for voluntary contributions, was wholly for the support of the poor Moslems; it might not be used for the maintenance of the state, i.e. Mahomet and his family. For them, and for public business, e.g. the purchase of war material and gratuities to visitors, proviso, was made out of the booty, of which Mahomet claimed one-fifth (the chieftain's share had previously, we are told, been one-fourth), while the remainder—or at least the bulk of it—was distributed among the fighting men; the Prophet appears to have prided himself on the justice of his distribution on these occasions, and doubtless won popularity thereby, though we hear occasionally of grumbling; for difficulties occurred when a defeated tribe embraced Islam, and so could claim equality with the conquerors, or when portions of the spoil were found irrationally excluded by Mahomet to alien recipients; the persons whose allegiance was thus purchased were euphemistically termed "those whose hearts were united." What afterwards proved the main source of revenue in Islamic states dates from the taking of Khaibar; for the rent paid to the state by tolerated communities for the right to work their land developed long after Mahomet's time into a poll-tax for Unbelievers (see Caliphs, e.g. B. § 8 and Mahomedan Institutions), and a land-tax for all owners of land. Immediately after the taking of Khaibar certain communities, of which the most notable was Fadak, sent tribute before they had been attacked and reduced; their land was regarded by Mahomet as his private domain, but after his death it was withdrawn from his heirs by his successor Abu Bekr, in virtue of a maxim that Prophets left no inheritance, which in the opinion of Fatinah was contrary to Koranic doctrine, and invented by Ayeshá's father expressly for the purpose of excluding her and her husband from their rights; and this is likely to have been the case.

As a military organizer Mahomet, as has been seen, was anxious to have the advantage of the most advanced methods, and more than once is said to have scandalized the Arabs by foreign innovations, as at a later time the Moslem chiefs who first used gunpowder scandalized their co-religionists. The unit in his armies seems to have been, as of old, the tribe, under its natural leader; he that introduced no more scientific division, and nothing like a hierarchy of officers was perhaps due to the difficulty of reconciling such a system with the equality of all Moslems.

As has been seen, the Koran only assumed the character of a civil code as the need for one arose; and for some time after Mahomet's arrival at Medina old-fashioned methods of settling disputes continued in use, and doubtless in accordance with precedent where such was known. For difficult cases, even in Arab opinion, divine inspiration was required; and since Mahomet naturally claimed to be in sole enjoyment of this, his utterances soon became the unique source of law, though he did not at first think of organizing a code. Such a plan is said to have occurred to him, and he even wished to dictate a code upon his death; but his friends supposed or professed to suppose him to be delirious. A table regulating the "Alms" was left by him, it is said, in the possession of Abu Bekr; but other traditions assign another origin to this document.

Just as there were no regular officials for the arrangement of business, so there were none for its execution; when punishment was to be administered, any follower of Mahomet might be called upon to administer it. In the case of the massacre of the Banû Qurayzah care was taken to see that some of the heads were struck off by their former allies, in order that the latter might be unable at any time to bring a demand for vengeance. The Prophet hoped by the mere terror of his name to make complete security reign throughout Arabia, and there is no evidence that any system of policing either it or even Medina occurred to him.

Until the death of Khadija the Prophet's private life seems to have been normal and happy, for though the loss of his sons in infancy is mentioned as a cause of great sorrow, he professed to have earned to some extent the favour of Zaid b. Harithah, apparently a prisoner ransomed by Khadija or one of her relatives, who appears as dutiful almost to excess and competent in affairs. The death of his mother seems to have been a blow to him, with, curiously, the exception of that between Fatinah and Ali. His domestic troubles, to which an unreasonably ample of space seems to be devoted, even in the Koran, began after the Migration, when, probably in the main for political reasons, he instituted a royal court, to which these were now referred, and it was from long survival, that the conquest of a state was consummated by possession of the former monarch's wife, or daughter; another, as has been seen, the desire to obtain the securest possible hold on his ministers. In his marriage with the daughter of his arch-enemy Abû Sofiân, before the latter's conversion, we can see a combination of the two. Few, therefore, of these marriages occasioned scandal; yet public morality seemed to be violated when the Prophet took to himself one of his adopted sons Zaid, whose name has in consequence the honour of mention in the Koran in the revelation which was delivered in defence of this act. Its purpose was, according to this, to establish the difference between adoptive and real filiation. The issue was occasioned by a charge of adultery brought against the youthful favourite Ayeshá, and this had to be refuted by a special revelation; the charge, which was backed up apparently by Ali, seems to have been connected with some deeper scheme for causing dissension between the Prophet and his friends. Yet another step in this case was that which illustrated the system organized by Omar's daughter Hafsa, owing to undue favour shown to a Coptic concubine (Mary, mother of a son called Ibrahim, who died in infancy; his death was marked by an eclipse, January 27, 632); and various details concerning the wives are told us by Mahomet's biographers.

Of the members of this harem the only prominent one is Ayeshá, married to the Prophet shortly after the Flight, when she had scarcely passed ten years of age, and was in all probability gifted with astuteness and ambition that were quite beyond her years, and who maintained her ascendancy over the Prophet in spite of the fact that many carping criticisms of his revelations are attributed to her. Some of these have been already noticed (see the text on pecuniary obligations) under which her father had laid Mahomet; but her reputation seems to have been greatly enhanced by the sending down of a revelation to exonerate her (A.H. 6), for which she thanked God and the Prophet. Each accession to the harem rendered the building of a house or room necessary for the newcomer's accommodation; a fact in which Robertson Smith perhaps rightly saw a relic of the older system whereby the tent was the property of women. The trouble noticed above seems to have arisen from the want of a similar arrangement of accommodation, for the new system permits cohabitation. When Mahomet, whether in consequence of the fatigue incurred by the "Farewell Pilgrimage," or, as others think, by the working of some poison put into his food some months before his death, was seized by what he described as illness which proved fatal, it was to the house of Ayeshá that he was transferred (from that of another wife) to be nursed; and he apparently died in the arms of the favourite, on whose statements we have to rely for what we know of his last hours.

The traditional description of Mahomet is "of middle height, greyish, with hair that was neither straight nor curly; with a large head, large eyes, heavy eyelashes, reddish tint in his cheeks, thick-bearded, broad-shouldered, with thick hands and feet"; he was in the habit of giving violent expression to the emotions of anger and mirth. The supposition that he at any time suffered from physical weakness seems absolutely refuted by his career as a leader of difficult, dangerous and hazardous enterprises. Even after the end of his life his health was no worse; indeed, during his last years he exhibited a capacity for both physical and intellectual activity which implies a high degree of both health and strength; and without these the previous struggle at Mecca would have been impossible. During the five years which followed his death, he was liable to fits (epileptic or cataleptic) was intended to account for certain of the phenomena supposed to accompany the delivery of revelations; some of these however rest on very questionable authority; and the more that the more revelations give evidence of careful preparation rather than spontaneity.

The literary matter ascribed to the Prophet consists of (1) the Koran (q.v.); (2) certain contracts, letters and rescripts preserved by his followers; (3) the works of a variety of learned men, collected by traditionalists. The references in the Koran to a form of literature called "Wisdom" (risālah) suggest that even in the Prophet's time some attempts had been made to collect or at least preserve some of the last; the general uncertainty of oral tradition and the length of time which elapsed before any critical treatment of it was attempted, and the variety of causes, creditable and discreditable, which led to the wilful fabrication of prophetic utterances,
render the use to which No. 3 can be put very limited. Thus the lengthy description of the journey to heaven which Sprenger was inclined to accept as genuine is regarded by most critics as a later fabrication. It is very much to be regretted that the number of pieces justifying the views held by the Cistercians and the Friars, and that for these oral tradition was preferred to a search for the best documents, some of which may well have been in existence when the earliest biographies were written. Their style appears to have been plain and straightforward, though the allusions which they contain are not always intelligible.

In his personal relations with men Mahomet appears to have been able to charm and impress in an extraordinary degree, whence we may have to control persons like Omar and Khalid, who appear to have been self-willed and strong, and he and a single interlocutor to have been sufficient to turn many an enemy into a devoted adherent. Cases (perhaps legendary) are quoted of his being able by a look or a word to disarm intending assassins.

Also, high though he may have been, in his character, and his office might not be described as sovereignty, his interests appear to have lain far more in the building up and maintenance of empire than in ecclesiastical matters. Thus only can we account for the violent and sudden changes which he introduced into his system, for his temporary lapse into paganism, and for his ultimate adoption of the cult of the Black Stone, which, it is said, gave offence to some of his sincere adherents (e.g., Omar), and seems hard to reconcile with his tirades against fetish-worship. The same is indicated by his remark on the attitude of the worshipper towards the Moreh who had denounced Moslem and not its cordial acceptance, and his practice of at times buying adhesion. Even an historian so favourable to the Prophet as Prince Caetani recognizes that ultimately what he regarded as most important was what he did rather than what he said. This was, I think, his political side, and in general his system was not favourable to fanaticism (al-qhadah fi-l-din); he repeatedly gave permission for concealment of faith when the profession of it was dangerous; he took care to avoid institutions which, like the Jewish Sabbath, interfered seriously with military expeditions and the conduct of business, and permitted considerable irregularity in the matters of prayer and fasting when circumstances rendered it desirable. In his theory that Koranic texts could be abrogated he made wise provision against the danger of hasty legislation, which is usefully illustrated by his failure to provide for such abrogation after his death.

As has been seen, Mahomet claimed to introduce a wholly new dispensation, and a maxim of his law is that Islam cancels all that preceded it, except, indeed, pecuniary debts; it is not certain that even this exception always held good.

Hence his system swept away a number of practices (chiefly connected with the camel) that were associated with pagan superstitions. The most celebrated of these is the arrow-game, a form of gambling for shares in slaughtered camels, to which poetic allusions are very frequent. More important than this was his attitude towards the blood-feud, or system of tribal responsibility for homicide (whether intentional or accidental), whereby one death regularly led to protracted wars, which was considered dishonourable to take blood-money (usually in the form of camels) or to be satisfied with one death in exchange. This system he endeavoured to break down, chiefly by sinking all earlier tribal distinctions in the new brotherhood of Islam; but also by limiting the vengeance to be demanded to such as was no more than the equivalent of the offence committed, and by urging the acceptance of money-compensation instead, or complete forgiveness of the offence. The remembrance of pre-Islamic quarrels was visited by him with condign punishment on those who had embraced Islam; and though it was long before the tribal system quite broke down, even in the great cities which rose on ruins, still it seems to have quickly been resumed in the desert, his legislation in this subject rendered orderly government among Arabs possible.

Next in importance to this is the abolition of infanticide, which is condemned even in early Suras of the Koran. The scanty notices which we have of the practice are not altogether consistent; at times we are told that it was confined to certain tribes, and consisted in the burying alive of infant daughters; at other times it is extended to a wider area, and said to have been carried out on males as well as females. After the taking of Mecca this prohibition was included among the conditions of Islam.

In the laws relating to women it seems likely that he regulated current practice rather than introduced much that was actually new, though, as has been seen, he is credited with giving them the right to inherit property; the most precise legislation in the Koran deals with this subject, of which the main principle is that the share of the male equals that of two females. Our ignorance of the precise nature of the marriage customs prevalent in Arabia at the rise of Islam renders it difficult to estimate the extent to which his views on this subject were an improvement on what had been before. To this Muhammad family, unless our records are wholly misleading, did not differ radically from the Islamic; in both polygamy and concubinage were recognized and normal; and it is uncertain that the text which is supposed to limit the number of wives to four was intended to have that meaning. The "condition of Islam," whereby adultery was forbidden is said to have been ridiculed at the time, on the ground that this practice had never been approved. Yet it would seem that certain forms of promiscuity had been tolerated, though the subject is obscure. Against these services we must set the abrogation of some valuable practices. His unfortunate essay in astronomy, whereby a calendar of twelve lunar months, bearing no relation to the seasons, was introduced, was in any case a retrograde step; but it appears to have been connected with the abrogation of the sanctity of the four months during which raiding had been forbidden in Arabia, which, as has been seen, he was the first to violate. He also, as has been noticed, permitted himself a slight amount of bloodshed in Mecca itself, and that city perhaps never quite recovered its sacrosanct character. More serious consequences for the development of the community was his encouragement of the shedding of kindred blood in the cause of Islam; the consequences of the abrogation of this taboo seem to have been felt for a great length of time. His assassinations of enemies were afterwards quoted as precedents in books of Tradition. No less unfortunate was the recognition of the principle whereby atonement could be made for oaths. On the question how far the exclusion of women was enjoined or countenanced by him different views have been held.

Besides the contemporary documents enumerated above (Koranic texts, rescripts and authentic traditions) many of the events were celebrated by poets, whose verses were ostensibly incorporated in the form of biographies. 1 In Ishaq b. Manuel appears to have been of these are obelized as spurious, and, indeed, what we know of the procedure of those who profess to collect early poetry gives us little confidence in the genuineness of such odes. A few, however, seem to stand by the practice of polygamy, and the influence of the Mohammedans. Many of important events, or of those who had actually taken part in them, were eagerly sought by the second generation, and some of these were committed to writing well before the end of the 1st century. This is the practice of assigning pensions proportioned to the length of time in which the recipient had been a member of the Islamic community, led to the compilation of certain rolls, and to the accurate preservation of the main sequence of events from the commencement of the mission, and for the detailed sequence of the Flight, which presently became an era (beginning with the first month of the year in which the Flight took place). The procedure whereby the original dates of the events (so far as they were remembered) were translated into the Moslem calendar—for some reason, this symbol has been done—is unknown, and is unlikely to have been scientific.

Mahomet’s conduct being made the standard of right and wrong, there was little temptation to "whitewash" him, although the original biography by Ibn Ishaq; in the author of the abridgment omitted as scandalous. The preservation of so much that was historical left little room for the introduction of miraculous narrations; these therefore either belong to the obscure period of his life or can be easily eliminated; thus the number of the events of the early period is limited. The abridgment of the story of the adoption of the Koran by which Mahomet was decided, of the battles of Badr, Uthman, and Hoinan, and the death of Sa’d b. Mu’adh, would lose nothing by the omission of the angels and the devil, though a certain part is assigned to them of importance. An example of this is the expectation of biographies which were published when the 'Abbasids were regaining to have falsified history for the purpose of glorifying 'Abbas, their progenitor; the very small extent to which this expectation is justified is a remarkable testimony to their general truthworthiness.

The following dates are given by the Arabic historians according to their respective ages. For the reasons which have been seen it is impossible to obtain complete accuracy.

|---|---|---|
Wuṭāw. | Battle of Uhud. |
| 5. | Šaḥābīn 2. | Attack on the Musalabīl (according to the Buṣaidī). |
| 7. | Šaffar. | Massacre of Mahomet's 70 missionaries at Bilḥamānah. |
| 8. | Šaffar. | Massacre of the Banū Qurayzah. |
| 10. | Šaḥābīn 1. | Futtle attempt to assassinate Abū Sofān. |
| 11. | Šaḥābīn 1. | An attempt to murder *Muqaddam. |
| 15. | Šaḥābīn 1. | Expedition to Ṭaʾīf. |
Ramaḍān. | Tālib expedition to the United Banū Ḥamīdah. |
| 17. | Šaḥābīn 1. | Farewell Pilgrimage. |

Companions of the Prophet.

The saḥābah, as they are called, are the subject of a vast literature, and the biographical dictionaries devoted to them, of which the best known are the Usd al-ḥābih of the historian Ibn Athir and the Ishārāt of Ibn Ḥajar al-Asqalānī, enumerate many thousands. The following two lists are of special groups:—

Abolition of idolatry in Arabia. |

Expedition ordered by Mahomet against the Byzantines.

<td>IBN SEYYID ABDULLAH, Sudanese tyrant, known as “the Mahdi,” was born in Dongola. His family, known as excellent boat-builders, claimed to be Aṣkrāf (or Shefri), i.e., descendants of Mahomet. His father was a fāki or religious teacher, and Mahomet Ahmed devoted himself early to religious studies. When about twenty years old he went to live on Abba Island on the White Nile about 150 m. above Khartoum. He first acquired fame by a quarrel with the head of the beyahdah which he had joined, Mahomet assenting to his master convicted of transgression of the divine law. After this incident many devotional (religio menandic) gathered round the young shiek, whose repagation for sanctity speedily grew. He traveled secretly through Koros, when (with ample justification) he denounced to the villagers the extortion of the tax-gatherer and told of the coming of the Mahdī who should deliver them from the oppressor. He also wrote a</td>

pamphlet summoning true believers to purify their religion from the defilements of the “Turks” *i.e.* the Egyptian officials and all non-native inhabitants of the Sudan. The influence he gained at length aroused the anxiety of the authorities, and in May 1881 a certain Abu Saud, a notorious scoundrel, was sent to Abba Island to bring the sheik to Khartum. Abu Saud’s mission failed, and Mahmood Ahmed no longer hesitated to call himself al-Mahdi al-Montasir, “The Expected Guide.” In August he defeated another force sent to Abba Island to arrest him, but thereafter deemed it prudent to retire to Jebel Gedir, in the Nuba country south of Kordofan, where he was soon at the head of a powerful force; and 6000 Egyptian troops under Yusuf Pasha, advancing from Fashoda, were nearly annihilated in June 1882. By the end of 1882 the whole of the Sudan south of Khartum was in rebellion, with the exception of the Bahal-el Ghazal and the Equatorial Provinces. In January 1883 El Obeid, the capital of Kordofan, was captured. In the November following Hicks Pasha’s force of 10,000 men was destroyed at Kashghil, and in the same year the mahdi’s lieutenant, Osman Digna, raised the tribes in the eastern Sudan, and besieged Sinkat and Tokar, near Suakin, routing General Valentine Baker’s force of 2500 men at El Teb in February 1884. The operations undertaken by Great Britain in face of this state of affairs are narrated under EGYPT: Military Operations. It need only be added that General Gordon (q.v.) was besieged at Khartum by the mahdi and was killed there when the town was captured by the mahdists on the 25th–26th of January 1885. The mahdi himself died at Omdurman a few months later (June 22, 1883), and was succeeded in power by his khalifa Abdullah.

When he announced his divine mission Mahmood Ahmed adopted the Shi’ite traditions concerning the mahdi, and thus put himself in opposition to the sultan of Turkey as the only true commander of the faithful. To emphasize his position the mahdi struck coins in his own name and set himself to suppress all customs introduced by the “Turks.” His social and religious reforms are contained in various proclamations, one of which is drawn up in the form of ten commandments. They concern, chiefly, such matters as ritual, prayers, soberness in food and drink, the cost of marriage and the behaviour of women. How far the mahdi was the controller of the movement which he started cannot be known, but from the outset of his public career his right-hand man was a Baggara tribesman named Abdullah (the khilafa), who became his successor, and after his flight to Jebel Gedir the mahdi was largely dependent on his support on Baggara sheikhs, who gratified one of his leading tactics by giving him numbers of their young women. In the few months between the fall of Khartum and his death the mahdi, relieved from the incessant strain of toil, copied in his private life all the vices of Oriental despots while maintaining in the public the austerity he demanded of his followers. His death was variously attributed to disease and to poisoning by a woman of his harem. On the occupation of Omdurman by the British (Sept. 1898) the mahdi’s tomb was destroyed, his body burnt and the ashes thrown into the Nile (see Sudan: Anglo-Egyptian).

See Mahdisim and the Egyptian Sudan by F. R. Wingate (1911); Ten Years’ Captivity in the Mahdi’s Camp (1882–1892) from the MS. of Joseph OOhrwalder by F. R. Wingate (1912) and For the Sword in the Sudan (1879–1895) by Slatin Pasha (trans. F. R. Wingate, 1896). Both OOhrwalder and Slatin were personally acquainted with the mahdi, and their narratives contain much first-hand information. Wingate prints many translations of the proclamations and correspondence of the mahdi.

**MAHOMMEDAN INSTITUTIONS.** Of all the institutions of Islam the caliphate is the oldest, the most fundamental, and in essence the most enduring. For its history see CALIPHATE: the present subject is its origin and nature. Mahomet enjoyed absolute rule over his people as a divinely inspired and guided prophet. He led the public prayers; he acted as judge; he ruled. If he consulted with others or paid attention to public feeling or local usage, it was as a matter of policy; the ultimate decision lay with himself. He was the state. On his death a leader was put in his place of similar authority, though without

the divine prophetic guidance. He was called the “successor” (*khulfa*, caliph) of the Prophet, later also the *amir-al-mu’minin*, commander of the faithful, and was elected by the Moslems, just as the Arab tribes had always elected their chiefs. He was thus an absolute ruler, but was democratically elected; and such is the essence of the caliphate among Sunnite Moslems to this day. For them it has been a matter of agreement (see MAHOMMEDAN LAW) from the earliest times that the Moslem community must appoint such a leader (see IMAM). The Shi’ites, on the other hand, hold that the appointment lies with God, and that God always has appointed, though his appointment may not always have been known and accepted. Their position may be called a legitimist one. Some few heretical sects have held that the necessity of a leader was based on reason, not on the agreement of the community. But, for all, the rule of the leader thus appointed is absolute, and all authority is delegated from him and, in theory, can be assumed by him any time. Just as God can require unreasonable obedience from his creatures (his “slaves” in Arabic), so can the caliph, his representative on earth.

But Abu Bekr, the first caliph, nominated his successor, Omar, and that nomination was accepted and confirmed by the people. So a second precedent was fixed, which was again carried a step further, when Moawiya I., the first Omayyad caliph, nominated his son, Yazid I., as his successor, and caused an oath of allegiance to be taken to him. The hereditary principle was thus introduced, though some relics of the form of election persisted and still persist. The true election possible in the early days of the small community at Medina became first a formal acceptance by the populace of the capital; then an assertion, by the palace guard, of their power; and now, in the investiture of the sultans of the Ottoman Turks, who claim the caliphate, a formal ceremony by the *ulumâ* (q.v.) of Constantinople. The Ottoman claim is based on an asserted nomination by the last Abbasid, who died in exile in Egypt in 1338, of the Ottoman sultan, Suleiman the Great, as his successor. Such a nomination in itself was a perfectly legal act, but in this case had a fatal flaw. It is an absolute condition, laid down in tradition, that the caliph must be of the tribe of Koreish (Quraish), that of the Prophet.

The duties of this democratically elected autocrat are, in theory, generally stated as follows. He shall enforce legal decisions and maintain the divinely revealed restrictive ordinances; guard the frontiers and equip armies; receive the alms; put down robberies, thieving, highwaymen; maintain the Friday services and the festivals; decide disputes and receive evidence; reconcile the religious and social claims; marry minors, male and female, who have no guardians; divide booty. He must be free, male, adult Moslem; must have administrative ability; must be an effective governor and do justice to the wronged. So long as he fulfils these conditions he is to be absolutely obeyed; private immorality or even tyranny are not grounds for deposing him. This is a position reached by Islam practically. But a caliph who openly denied the faith would be as impossible as an unbelieving pope. The caliph, therefore, is the highest executive officer of a system assumed to be definite and fixed. He, in a word, administers Islam; and the content of Islam is determined by the agreement of the Moslem people, expressed immediately through the *ulumâ*, and ultimately, if indirectly and half-consciously, by the people. To depose him a *fatwa* (see MUFET) would be required—in Turkey, from the Sheikh-ul-Islam—that violated some part of the Moslem faith, and no longer fulfilled the conditions of a caliph.

But it was impossible for the caliph personally to administer the affairs of the empire, and by degrees the supreme office was gradually put into commission, until the caliph himself became a mere figurehead, and vanished into the sacred seclusion of his palace. The history of the creation of government bureaus (*divans*; see DIVAN) must therefore now be sketched. The first need which appeared was that of a means of regulating and administering the system of taxation of the state. Imams were appointed into Medina from the Arab conquests; the surplus, after the requirements of the state were met, was distributed among the believers.
MAHOMMEDAN INSTITUTIONS

All Moslems had a right to a certain share of that which was regarded as booty. Omar, the second caliph, regulated this distribution and also the system of tax, and the result was the first divan and the constitution of tax, which took to be now by all Moslems. The tax, as it was called, was a poor-rate (zakāt), a tithe paid by every Moslem; (ii) the fifth of all booty; (iii) the poll-tax (jizya) on non-Moslems; and (iv) the land-tax (kharij) also on non-Moslems. Thus the constitution determined the lot of all Moslems. There was a provision that the Moslems should be kept apart as a superior, fighting caste, and that the non-Moslems should support them (cf. CALIPHATE, B. § 8, on the reign of Omar II.). The Moslems, therefore, were forbidden to intermarry with the non-Moslems. They were required to retain their lands, cultivate them and pay the land-tax (the Arabic word is also used revenue of the work of a slave) and the poll-tax (the Arabic word means also ‘ransom’), and give contribution to the support of the Moslem army. The Moslems were massed in great camps at strategic points. If a non-Moslem embraced Islam he entered the ruling caste; his land was distributed among his non-Moslem fellows, and he no longer paid the land-tax but rather received support from the public funds.

The amount of these pensions varied with the standing of the pensioner from 10,000 dirhems (a dirhem equal to a franc) to the widows and relations of the Prophet down to 300. This bureau, therefore, not only to keep the books of the state, but also to maintain a list of all Moslems, classified genealogically and socially. Its registers were kept by Greeks, Copts and Persians; the Arabs, it may be said in general, adopted the method of administration ruling in their own countries and drew upon the trained services of their inhabitants.

Such a system led naturally to wholesale conversions to Islam; and the consequent decline in revenue, combined with large donations to the poor, so that the state, which was gradually broke down it. The first patriarchal period of conquest, unearned wealth and the simple life—called by Moslems the period of the ‘four rightly guided caliphs,’ and very happily by Sachau, was not a period of great government. The caliph was the center of the empire of the Omayyads, with whom came an immediate development of organization in the state. The constructive genius in this was Moawiya, the first Omayyad caliph. Under him the simplicity vanished. A splendid and ceremonial court was established at Damascus. A chamberlain kept the door; a bodyguard surrounded the caliph, and even in the mosque the caliph, warned by the congregation of his importance, refused to return in a public prayer. The beginning of the seclusion of the caliph had come, and he no longer walked familiarly among his fellow Moslems. This seclusion increased still further when the administration of the state passed by direct action of the caliph, acting in the name of his son and his heir. The caliph himself became a potent figure-head, as in the case of the later Abbasids; when theories of semi-divine nature and of theocratic rule appeared, as in the case of the Fatimites; and finally when all the elaborate court rituals were carried in a fashion least a Somalian.

But Moawiya I. was still a very direct and personal ruler. He developed a post-system for the carrying of government despatches by relays, and thus received secret information from and kept contact with provincial governors. A post-service bureau by which state papers were secured against change. He dealt arbitrarily with the revenues of the state and the pensions of the Moslems. Governors of provinces were given a much freer hand, and were required to turn over to the central treasury their surplus revenue only. As they were either conquerors or direct successors of conquerors they had an essentially military government, and were really semi-independent rulers, unhappier except by direct action of the caliph, acting in the name of his son and his heir. He was his local spy. Being thus the heads of armies of occupation, they were not necessarily charged with the control of religious ritual and of justice. These, like every other function, in the hands of the caliph. They were ruling officials of an army, of the province independent califs or the courts and in many to be in charge of religious services. Yet the governor was sometimes permitted to hold these two offices (see CAD; IAM).

Further administrative developments came with the Abbasids. They created a new city, Bagdad, between the Tigris and the Euphrates, where the three races, Syrian, Arab and Persian, met and sought with Bagdad as a capital to consolidate the empire. The Arab empire, it is true, had passed away with the Omayyads; yet there might be a chance to create a world-empire of all the Moslem peoples. But not even the genius and administrative skill of the early Abbasids could hold together that unwieldy mass. The semi-independent provinces soon became fully independent, or at most acknowledged the caliph as a spiritual head and paid a nominal tribute. His name might stand on the coinage and prayers be offered for him in the Friday service, the two signs of sovereignty to this day in Islam. With this crumbling of the empire went a more elaborate organization; bureaus took the place of principles and of the energy of individual rulers. As the system of Moslem law was built on that of the Roman codes, so was the machinery of administration on that of Persia. And with the Abbasids the chance of the Persians had come. Abū l-Abbās, the first Abbasid caliph, was the first to appoint a vizier (wāsit, ‘helper’), so Aaron is the wāsit to Moses in the Koran), a confidential minister to advise him and come between him and the people. Advisers the caliphs had had before; but not a definite adviser with this name. He must, we are told, have a strain of the ruler in him and a strain of the people to be able to work with both. He must know how to be acceptable; fidelity and truthfulness are his capital; sagacity, firmness, generosity, clemency, dignity; effectiveness of speech is essential. It is plain that the vizier became as important as the caliph. But Abū l-Abbās was fortunate in early securing as his vizier the grandchild of the house of the Barmaçides (q.v.). On this Persian family the Abbasids leaned. The Abbasids hung, and it secured for them and for Islam a short golden age, like that of the Antonines, until the jealous madness of Hārūn al-Rashīd cast them down. Thereafter the vizierate had many vicissitudes. Technically a vizier could be either limited or unlimited. The limited vizier had no initiative; he carried out the commands of the caliph. The unlimited vizier, often afterwards called the grand vizier, exercised full authority and was the alter ego of the caliph, to whom he was required only to report. Naturally the formal distinction is a later theorizing of history; for a weak ruler his vizier became absolute, for a strong ruler his vizier remained subordinate. Here, as with regard to all Moslem institutions, a marked distinction must be made between the historic facts and the speculative theories raised by contemporary theorists. Compare especially the MAHOMMEDAN LAW. Until the time of Rādī (934–940) the vizierate thus fluctuated in importance. In that caliphate the vizier lost all authority, and in his place came the amīr al-omarā’—equivalent to the major domo of the Franks—the head of the Turkish bodyguard, in terror of whom the caliph now stood. In 945 the Buyids captured Bagdad and the caliph became a purely spiritual sovereign, they took the title ‘vizier’ for their own chief minister, and the caliphs retained only a secretary (see CALIPHATE, C. § 22). Under the Seljuks, however, they regained their viziers and some real authority. Elsewhere, also the vizierate had its vicissitudes. Under the Mamelukes the vizier fell to be merely the court purveyor. Under the Omayyads of Spain the title was given to several responsible ministers of the state, but their chief was called ḥāfīb, chamberlain. Under the Abbasids the vizier of the caliph was called generally ḥāfīb. In the modern Turkish empire the grand vizier (called generally pasha or aṣām) is the sultan’s representative in secular matters, and nominally stands between the sovereign and the other officials. He is the president of the council of ministers, but Abd-ul Hamid II. deprived the office of almost all its importance.

Under the early Abbasids the four most important ministers were the chief cadi, the chief of police or head of the life guards, the minister of finance and the postmaster, who was the chief of the postal system. Only rarely did the vizier covered the empire. But at different times the different bureaus varied greatly. Under Mutasāwīkki we find the bureau of taxes and finance; bureau of the castle estates; bureau of state books; bureau of the post and vizier; group of bureaus, which kept reckoning and control of the pensions of the clients and slaves of the ruling family; bureau of the post; bureau of expenditures. But in spite of this elaborate system, no Moslem government has, except sporadically, been highly centralized. Provided the taxes are paid, a large measure of local autonomy has always been enjoyed by the country districts. Under the Abbasids that the one exception was the necessarily centralized control of the irrigation system of the Tigris and Euphrates, and similarly elsewhere.

In the case of all these offices, we have delegation by the caliph, under necessity; of his too heavy burdens. But one duty of a vizier was not to let him be. The vizier, could be possible for the oppressed to come into his presence and claim justice; he must sit in the gate and judge. Therefore, when the caliph found it necessary to delegate the ordinary administration of justice, he found it also necessary to set up a special court of appeal, which developed, to a certain extent, into a court of appeals. The first to establish such a separate court was Abd-al-malik the Omayyad
MAHOMMEDAN INSTITUTIONS

(685-705), and his example was followed by the more vigorous of the caliphs up to the time of Mohtadi the Abbasid (869-870). If any other than the caliph presided over this court it had to be a man whose dignity, independence and authority commanded respect. He was the supreme judge, and he pronounced the rules of evidence and procedure, and the application of law as was the caliph. Rather, he applied a system of equity suited to the absolute source of authority which he represented. As the chief of police, mentioned above, was rather the head of the caliph's bodyguard, the ulamas also held, not the system after which it was named, but more thoroughgoing.

The Maktab had charge in the broadest sense of public order and morals in the streets, and had oversight as to weights, measures and adulterations; but had no right to interfere privately in the domestic morals of the Moslem household. He had a summary jurisdiction in all minor cases where no trial was necessary; but where witnesses and oaths entered the case must go to the caliphal courts. Slaves and beasts of burden were under his guardian-ship; he was protector of widows and orphans, and of the public order. He had charge of the public conduct of Jews and Christians. In the interest of public morals he had to find suitable husbands for widows and see that they did not marry before the legal time; questions of patronage also he had to investigate. The outdoor army was to be under his direction also. It should, of course, be remembered that the caliph was the supreme judge in the Moslem law.

It is impossible in Islam to separate logically from the mass of institutions those which we should call religious, as Islam on all sides is the Moslem equally religious. But perhaps the following may perhaps be considered under the rubric of runs, in that it is based on the theory that there is no god save Allah, and that Mahomet is the apostle of Allah; prayer; the poor-rate; pilgrimage; fasting. For these see Mahomedan Religion.

The law and usage of religious foundations in perpetuity (waqf, mortmain) became as important in Islam as monastic endowments in medieval Europe, and such foundations tended similarly to absorb the greatest bulk of the Moslem people's wealth. Their well-considered system for providing for posterity. A pious foundation could be erected in such a way that either so much from its funds would be paid yearly in perpetuity to the descendants of the orators, or the descendants would be employed in the details of the management of the waqf.

When it became impossible for the caliph to lead people personally in prayer in the mosque, he delegated that part of his duties to another, hence called imam (q.v.). Naturally, when this appointment of the imam would lie with the supreme ruler. This hold of the title al-masijd al-jami' (the great mosque) is supported by the rule that the Friday service is held, but in the separate smaller mosques built by each community the community itself determines its own imam. With regard to the latter choice, the same rule is to be followed as to the ministers of the presence of an imam appointed by the chief ruler. The imam should certainly make mention of the ruler in his sermon and pray for him. He should, at the occasional prayers, such as those for rain, etc., the peace and prosperity of the nation; in all cases noted before, the imam appoints the muadhdhin, the announcer of the hour of prayer from the minaret, and both have a claim on the state treasury.

Another office exercised when possible by the caliph, but very frequently by the Amir al-Kashef (q.v.) was the duty of providing the government with the call to prayer, such as to the caliphate or a prince, was the leadership of the pilgrimage caravan to Mecca and back. Sometimes this official, called amir al-kaff, was appointed imam as well. He then led all the pilgrimage ceremonies at Mecca. When outside of towns, there was a cadi he exercised also over the caravan the rights of a judge. Mahomedan law (q.v.) is treated separately. Here, again, as judging is a duty of the caliph, a cadi is the delegate, or, when appointed by the Amir al-Kashef or his lieutenant, he exercises the office of the cadi. He examines into disputes brought before him and enforces his judgments, he names administrators of the estates of the caliphate, the insane, etc.; he supervises the waqf property of mosques and monasteries, and inspect public buildings; he watches over the execution of wills; he inflicts the due legal penalties for apostasy, neglect of religious duties, refusal to pay taxes, theft, adultery, outrages, murder; he can inflict the penalties of imprisonment, fine, corporal punishment, death; if there is no imam, he can perform his duty, as in fact can anyone who has the requisite knowledge. But it should be noticed that all this holds only of the un-Europeanized Moslem state.

The existence of an army in Islam, there are two grounds, the holy war (jihad, q.v.) against unbelievers without the state and the suppression of rebellion within. Under the ordinance of Omar the entire community was preserved and used as a weapon for the subduing of the world to Islam, and every able-bodied Moslem was theoretically a fighting man, part of the national militia. This army was divided into corps situated in the conquered lands, as armies of occupation, where they eventually came to form military colonies in great camp-cities. The occupied countries had to support them, and they were bound to render military service at any time. But as the ideal of Omar broke down before facts the use of mercenary and slave troops finally increased; although there has always continued in Moslem armies acting against unbelievers a proportion of volunteers not paid a fixed wage but subsidized by the state from the poor-rate and alms funds. The generals were appointed by the caliph, and had either unlimited authority to act as his representatives, concluding peace, acting as cadi and imam, distributing booty; or were restricted within limits, e.g. to simple leading of the troops and carrying on military operations. They, in turn, appointed their subordinates; this principle of giving a head full powers and full responsibility was very generally applied in Islam. It was controlled of course by the espionage of the postal system. As war by a Moslem power is essentially sacred war, the regulations of jihad must be considered here. Unbelievers must first be invited to embrace Islam and, if they follow a sacred book and are not idol worshippers, are given a choice between (a) becoming Moslems; or (b) submitting to the Moslems and entering on a treaty with them of protection and tribute; or (c) fighting. If they accept Islam, their lives, families and property are secure, and they form henceforth part of the Moslem community. The ability of Islam to create a common feeling between highly different races is one of its most striking features. If they submit and enter on treaty relations, they pay a poll-tax, for which their personal safety is assured, and assume a definitely inferior status, having no technical citizenship in the state, only the condition of protected clients (dhimmis). If they elect to fight, the door of repentance is open, even when the armies are face to face. But after defeat their lives are forfeit, their families are liable to slavery, and all their goods to seizure. It is open to the sovereign either to put them to death; or to enslave them; or to give them their liberty; or to exchange them for ransom or against Moslem prisoners. The sovereign will choose the best for Islam, whether his own family or wealth, the sovereign can release them only with consent of the army that has captured them. Apostates must be put to death. Fourths of the booty after a battle goes to the conquering army.

The technical art of war seems to have been little studied among Moslems; they have treatises on archery but very little upon tactics. Their writers recognize, however, the essential difference between the European and Persian methods of charging in solid lines and holding the ground stubbornly, and the Arab and Persian method of flying attacks and retreats by clouds of cavalry. Therefore, one explained, the custom grew of using a mass of European mercenaries as a fixed nucleus and rallying-point. The early Moslem armies, too, had used the solid, unyielding charge, which may have been the secret of their success. For one of the greatest puzzles of history is the cause which changed the erratic, untrustworthy swarms of Arab horsemen with their childish strategy into the ever-victorious legions of the finest cavalry. They certainly learned rapidly. Education and technical education has never been recognized in Islam. There was no primary education, nor secondary deployment and knowledge. Apparently, if we may trust the many stories of how ignorant men set up for themselves, there was no control of them by the state. Their pupils were young only; they taught the rudiments of the Koran, were able to write, but perhaps a little of the latter. Technical education was given by the gilds through their apprentice system, teaching mechanical arts and crafts. This was genuine instruction, but was not so regarded; it was looked upon rather as the mysteries and secrets of operative masonry. It produced artisans of independent character, but not artists. Thus there was no distinct separation between architect and builder; there was no sculpture; and painting, so far it went, was like carving, a craft. All Moslem university education, like all Moslem
With the death of Mahomet began the development and codification of Moslem law. It was at first entirely practical. Cases had to be decided, and to decide them there was, first, the Koran; secondly, if nothing ad litem was found in the Koran, there were the decisions of the Prophet; thirdly, if these failed, there was the common law of Medina; and, fourthly, if it, in turn, failed, the common sense of the judge, or equity. A knowledge of the decisions of Mahomet came thus to be of great importance, and records of such decisions were eagerly sought and preserved. But this was simply a part of a much wider movement and tendency. As among primitive peoples in general, custom and usage have always been potent among the Arabs. The ways of the fathers, the old paths, they love to tread. Very early there arose a special reverence for the path and usage (sunna) of Mahomet. Whatever he did or said, or left unsaid or undone, and how he did it, has become of the first importance to the pious Moslem, who would act in every way as did the Prophet. There is evidence that for this purpose the immediate companions of Mahomet took notes, either in memory or in writing, of his table talk and wise sayings, just as they took down, or learned by heart for their private use the separate fragments of the Koran. His sayings and doings, manners and customs, his answers to questions on religious life and faith, above all his decisions in legal disputes, came to be recorded on odd sheets in private notebooks. This was the beginning of the enormous literature of traditions (hadith) in Islam. The collecting and preserving of these, which was at first private, for personal guidance and edification, finally became one of the most powerful weapons of political and theological propaganda, and coloured the whole method and fabric of Moslem thought. All knowledge tended to be expressed in that form, and each element of it to be traced back to, and given in the words of, some master or other through a chain of transmitters. Above all there grew up an enormous mass of evidently forged sayings put into the mouth of Mahomet. At every important political or theological crisis each party would invent and put into circulation a tradition from him, supporting its view. By a study of these flatly opposed “sayings” it is possible to reconstruct the different controversies of Islam in the past, and to discover what each party regarded as the essence of its position.

The first collecting of traditions was for private purposes, and the first publication dealing with them was legal. This was the Muwatta of Malik ibn Anas (d. 795), a corpus juris based partly on traditions, and a protest in its methods against the too speculative character of the Zahiris. Malik’s law was the first attempt to combine collections of two different types. The earlier kind was according to the companions of Mahomet, on whose authority the traditions were transmitted; after each companion came the traditions going back to him. The best known example of this kind is the Muhammah ibn Hanbal. The other kind, called Musannaf (classified), contains traditions arranged in chapters according to their subject matter. That of Bukhârî is the most famous, and is arranged to give a rational basis for a complete system of canon law; its rubrics are those of such a system. Another is that of Muslim ibn al-Hajjâj, who paid less attention to legal aspects and more to minute accuracy. There are many others of more or less acceptance and can serve as a basis for the others. Christians and Jews, dealing with the development of the law of Moses directly affected by Roman law; at another, the more developed commercial law of Mecca, known to his followers who had fled with him; or, finally, his own personal judgment, stated it might be as his own sense of right or as the decision of Allah and even incorporated in the Koran. In his use of these he was an eclectic opportunist, and evidently, except as regards such frequently recurring subjects as inheritance, marriage, &c., had no thought of building up a system or code. At his death he left behind only a few specific prescriptions in the Koran and a mass of recorded decisions of cases that had come before him. He had used himself, in our terms, common law, equity, legislation; to guide his followers he left his legislative enactments and the record of his use of common law. Since his death there has been no new legislation in orthodox Islam.

MAHOMMEDAN LAW. The legal situation in the Moslem world is of the highest complexity, and can be made intelligible only by tracing its historical development. First came the system (fiqh, sharia) which takes the place in Islam of canon law in Roman Christendom. It begins with Mahomet sitting as judge over the primitive Moslem community at Medina. He was the Prophet of God, and judged, as he ruled, absolutely; any decision of his was valid. But he, in general, advisable and fitting to follow the local law or usage of Medina, when the new faith did not require a change. It thus came about that his decisions followed, at one time, the usage of the Arab tribes of Medina; at another, the law of Egypt, and at a third, the law of Damascus. It was that of the law of Moses slightly affected by Roman law; at another, the more developed commercial law of Mecca, known to his followers, who had fled with him; or, finally, his personal judgment, stated as his own sense of right or as the decision of Allah and even incorporated in the Koran. In his use of these he was an eclectic opportunist, and evidently, except as regards such frequently recurring subjects as inheritance, marriage, &c., had no thought of building up a system or code. At his death he left behind only a few specific prescriptions in the Koran and a mass of recorded decisions of cases that had come before him. He had used himself, in our terms, common law, equity, legislation; to guide his followers he left his legislative enactments and the record of his use of common law. Since his death there has been no new legislation in orthodox Islam.
they went, and it was the policy of their leaders to take over the administrative systems of the countries which they seized. Even the Arabic legal nomenclature shows evident signs of literal translation from Latin, and many Moslem principles can be traced to the Roman codes. One important development was plainly influenced by the liberty involved in the *Responsa prudentium* of Roman lawyers, and by the broad conception of the law of nature in the Edict of the Praetor. In its earliest stages Moslem law recognized in the judge a liberty of opinion (ra'y) which went beyond even that of the *Responsa* and became plain equity, in the English sense, and one school (the Hanifite) established as a basis the right of preference (istihsân) even when the analogy of the code dictated otherwise; while another (the Malikite) used the term istislah, "a seeking of (general) benefit" to the community, in a similar situation. But these developments were bitterly contested, and the liberty of opinion was in the end narrowed down to a principle of analogy (qiyâs), the nearest approach to which in Western law is legal fiction.

It is necessary now to return to the first successors of Mahomet. "For thirty years after my death," he is said to have declared, "my people will read in my path (waraṣma); thereafter will come kings and princes." This tradition crystallizes the later feeling of Islam. The first thirty years were a golden age; the centre of the state was the Prophet’s own city of Medina; the conditions of the state continued in close conformity to those of his own time. The study of tradition, i.e. of his usage, went hand in hand with the study of law. They were vital functions of the state, and it encouraged both.

Then came the great débâcle. The ancien régime, a semi-monkish, theocratic empire, went down, and the Omayyad dynasty, kings and princes of the old Arab type, took its place (see Caliphate, B). The public life of the state was no longer deeply religious; the pious said that it was godless. Under these conditions law was indeed still needed; but it had to be opportunistic. Its development went on, but became speculative. The study of tradition was now private, and its students were in most cases personally pious, but there were, thus, two results. On the one hand, the framers of systems of canon law—as it now was—no longer lived in contact with reality; hypothetical and ideal structures were reared which could never stand the touch of the practical law-court. And on another, traditions and law, even this hypothetical law, came to take separate roads. The interest of the students of tradition became the gathering of traditions for their own sake, going no farther than a striving to regulate each detail of life by some specific, concrete, prophetic dictum. They had no use for systems that went beyond the mere registering of these dicta. The feeling also became widespread that any system of government which did not simply reproduce the patriarchal form of Medina was of the world and the devil—a thing with which no religious man could have ought to do. At every turn he would have to peril his soul.

Here we must place the transition of this law with which we have hitherto dealt from being the law of the land to being in essence a variety of canon law. It was always broader than any western secular law. It regulated all the aspects of life—duty to God, to one’s neighbour, to one’s self. It was really a system of duties, ethical, legal, religious. It did not limit itself to defining the forbidden (haram); but designated actions also as required (lard, wâjih), recommended (mandub, mustahabb), indifferent (jâziz, mubâk), disliked (makrûh). It played the part of, or rendered necessary, a religious director quite as much as a lawyer. And for a time at Medina it was really the law of the land. But from the Omayyad period on it has held the position of the canon law of the Roman Church in countries that will not recognize it and yet dare not utterly reject it. It governs, in one or other of its four schools, the private lives of all pious Moslems, it regulates some semi-public relationships—e.g. marriage, divorce, inheritance; it compels respect, if not acceptance, from the state; and by its ideal standard the world, filled with righteousness by the Mahdi, will be ruled in the Moslem millennium.

The rise of the Abbasids brought a change, but not a great one. They had promised a return to the old religious attitudes, and the promise was formally kept. But in substance they were as much as the Omayyads, and though the state was outwardly on a pious footing, and the religious sentiment of the people was respected, the old, absolute canon law was not restored. It was made possible for more theologians and lawyers to work with the state, but an irreconcilable party still remained, and the situation was fixed as it is to this day. It is true that the struggle to adapt such a single and detailed system to all the varying conditions, climates and times of the great empire was impossible; but the failure marked the great rent in the supposed unity of Islam between the church and the world, religion and law.

Yet the Abbasids did, in their way, encourage legal studies, and under them processes and results, long pursued in private, became public. Almost within the first century of their dynasty the four legal schools, or rites, were formed and the principles established which survive to this day.

The first school to take definite form was the Hanifite, founded by Abû Ḥanîfa (d. 707), who left behind him a definite system and many enthusiastic pupils. He was a man of means, in touch with the world, and wrote important philosophical and philosophical jurists. Being of non-Arab origin, the usage of Medina had small interest for him. He therefore used few traditions, and preferred to go back to the Koran, and extract from it by reasoning the legal content (ijâda). This he put (qiyâs) into a rational system of analogies (istihsân); but, in his hands, it became practically legal fiction, the application of a law in some sense undreamed of its first imposer. But he had another, and still freer instrument. The effect of different circumstances, conditions, early periods, or periods in general terms. Abû Ḥanîfa reduced it to a subjective formula. Under such conditions he claimed the right of preference (istihsân) of a ruling suited to the local needs, even when the strict analogy indicated the opposite. He was, in fact, the first who took upon himself to define the rule of law, or the judgment, in any conceivable case. After his death his pupils elaborated it still further, and accepted public office. The ‘Abbasids adopted his school, and threw their influence on its side; its philosophic development, and this fact and his work, have far exceeded it to them. Later, the Ottoman Turks also adopted it, and it may be said to hold now a leadership among the four legal rites. Its influence has undoubtedly tended to broaden and humanize Moslem law.

Twenty-eight years after Abû Ḥanîfa, Malik ibn Anas, the founder of the Malikite school, died at Medina. In many points his situation was precisely opposite to that of Abû Ḥanîfa, and yet his results were very similar. He was a strict, working jurist, in practical touch with the life. He was in the centre of the tradition of the usage of the Prophet, and, he himself, perhaps, of the apostolic succession. He, therefore, used traditions much more generally than did Abû Ḥanîfa, and when he, under pressure, took refuge in opinion, he certainly felt that he, under his conditions, had a better right to do so than any outsider. But two of his principles marked a distinct advance and showed that he was no mere traditionalist. For one, he laid down the conception of public advantage (istihsân); when a rule founded on even a valid analogy would work a general injury it was to be set aside; justice must not be overcome by logic. And, for the other, he laid stress on the conception of the agreement (ijmâ‘), and which was of great importance in the future. When the surviving companions of the Prophet, and after his death, agreed upon any point as belonging to their store of tradition and experience, their agreement was accepted as final. In the first instance they agreed that such had been the statement of the Prophet. They then passed it to the general habit of opinion; and the true Moslem view, and finally into an acceptance of the principle that the Moslem Church, when unanimous, could formulate truth—practically as in the case of the law of Lèzards, Quod semper, quod ubique, and thus practically as it is now studied throughout the world. But still in the future, and for Malik, juristic agreement meant the agreement of Medina, though there are signs that he permitted the same latitude to other places also. It was a way of allowing for local conditions without infringing the general will. The result of these ideas was the *Mawâju‘*, the earliest in our possession written by the founder of a school, has already been mentioned. It is a collection of about seventeen hundred traditions of juristic importance, arranged according to subject, with appended remarks on the usage of Medina, and on his own view of each matter. So far opinion and local usage had fully held their own, and the philosophical jurist had been free to work out his system. The difference between the istihsân of Abû Ḥanîfa and the istislah of
Malik was not great; students attended the lectures of both and combined their systems. But a reaction now began, and the tradi-
tionalist party finally made itself felt. We have the inevitable rivalry between the historical-empirical and the speculative-philoso-
phical schools of jurisprudence, rendered all the more bitter in that the
historical lawyers believed, in this case, that they were defending
a divine institution. There resulted, first, one of the most important
schools, the Shāfiʿī; secondly, an extremely literal school for which as
a Greek historian said, "the Koran is the Epistle of God"; thirdly,
the Hanbalite school, still surviving in small numbers, more
moderately traditional than the last.

The school founded by ash-Šāfiʿī (d. 820), a pupil of Malik, came
first in order of time. The others were really revolts against the
mechanical legalism of his predecessors. His string of way- minded, steady grasp of means and ends, a perception of what could
and what could not be done, a willingness to admit all the tried
principles in due balance, and, at one point especially, the insight
of the magician over those of the jurists, threw stress on tradition;
à true, authentic tradition he regarded as no less
valid than the Koran itself. If the tradition was chronologically
later than a Koranic passage and corrected that passage, he followed
the tradition. But in this he was only regulating a principle.
The Koran may be regarded theoretically as the first of all the
sources of law and theology; practically its clear statements have been
over-riden in many cases. Most important of all, the principle
of agreement (ijmāʿ) came finally with him to its full rights. The
agreement of the Moslem peoples was to be the voice of God. "My
people," said a tradition from Mahomet, "will never agree in an error."
And so, over traditions and over the Koran itself, the agreement
of the Moslem people was a criterion not only logically
authoritative that which the other principles lay down. At
the head of each section of a Shāfiʿī law book we read, "The basis of
this, before the agreement, is such and such. But with the aid of a
principle of agreement (ijmāʿ) was added to it, it is possible
to reject an objectionable to the traditionalist party.
In its place he took analogy (gyūs), which, discreetly used, could serve almost the same
purpose. The Koranic passage or the tradition with which an
analogy was suggested should, said the learned; examiners in
theology should rate it for or against. If so, that
reason would give a basis for the analogy. Analogy based on the mechanical
or external could not hold.
The four bases thus laid down by ash-Šāfiʿī—Koran; prophetic
words; analogy; agreement—have come
to be accepted by all existing schools. This applies to all spheres
of life, ethical, social, theological, legal, and it should never be
forgotten that the Koran is only one of the sources for Moslem faith
and law.

Few words are needed for the other, reactionary schools. One,
now long extinct, was founded by a certain Dāʿūd uz-Zāhibī, "David
the Literalist," born three or four years before the death of ash
Shāfiʿī himself, and finally it was recognized as an article of faith in the
interpretation of his texts—Koran or tradition—without account
doctrine context or metaphor. In consequence he had to reject analogy,
and limited agreement to that of the companions of Mahomet; the
Oman, Tabari, and Ismaʿīlīs have other authors. At another
point he showed great sense of judgment, namely in his rejection
of the principle jurare in verba magistri, otherwise regnant in Islam.
His school had long and interesting consequences, mostly theological,
but is now extinct, and never took rank with the others. The Moslem
world had many and different schools. Each had its
prominent leaders, its traditions, and its distinctive
features and school of thought. Thus the Hanbalites
were the most popular, followed by the Imāmīs
and the Shāfiʿīs. The Hanbalites were the most popular,
while the Shāfiʿīs, the Hanbalites, and the Ismaʿīlīs
seemed to have been the most popular.
every Moslem country at least two systems of courts, the one administering this canon law, and taking cognisance of private and family affairs, such as marriage, divorce, inheritance, its officials also giving rulings on purely personal religious questions, such as details of the ritual law, the law of oaths and vows, &c.; the other, the true law courts of the land, administering codes based on local custom and the decrees of the local rulers.

A rift almost as important entered the legal life of the Moslem lands on another side. Non-Moslem communities, settled in Moslem territory, have been uniformly permitted to administer and judge themselves according to their own customs and laws. Save when they come into direct contact and conflict with Moslems, they are left to themselves with a contemptuous tolerance. The origin of this attitude in Islam appears to be threefold: (i) The Islam of theory cannot conceive of a mixed state; it takes account, only, of a state containing none but Moslems, and its ideal is that the whole world will, in the end, form such a state. In practice, then, Moslems try to shut their eyes to the existence of non-Moslems in their midst and make no provision for them until compelled. That a non-Moslem should have the same civil position as a Moslem is unthinkable. (ii) This, of course, produces an attitude of extreme contempt. The only citizens are Moslems and all others are to be looked down upon and left to themselves. What they do or think among themselves does not matter; they are outside the ring-fence of Islam. (iii) A different, but equally important, cause is the Moslem indolence. When the Arabs conquered, they knew that they must administer the conquered lands, and they, very wisely, sought help from the machinery they found in operation. But besides the ordinary organization of the state, they found also various ecclesiastical organizations, Christian and Jewish, and to these they gave over the administration of the non-Moslem sections of the community, making their rabbis and bishops their responsible heads and the links of contact with the Moslem rulers. They, unquestionably, found the same method in use by the Byzantine government; but in Moslem hands it went so far as to make a number of little states (millet, milidi) within the state, effectually to preclude the ever possibility of ever welding all the inhabitants of the land into corporate life.

But this indolence, when applied to resident aliens, had consequences still more serious, because external as well as internal. Following the same method of leaving the unbeliever to settle his affairs for himself, the European merchant, living and trading in the East, was put first by usage and finally by treaty under the jurisdiction and control of his own consuls. Thus there grew up the extra-territorial law of the capitulations and conventions, by which the sanctity of the person and household of an Arab was extended to every European. And this, in turn, has reacted on the status of the non-Moslem subject races, and has come to be the indirect but chief support on which they lean. Through it, an element has developed which makes it practically impossible for a Moslem state to introduce legal changes even remotely affecting its non-Moslem population, alien or subject, without the consent of the European empires. Any change may be upset by their refusal to accept it as incommis- patible with the capitulations and conventions. The embassies have thus, as interpreters of a part, at least, of the constitution, come to hold a position remarkably, if absurdly, like that of the Supreme Court of the United States (see Young, Corps de droit Ottoman, passim).

There may be said, then, in short, to be three elements in the legal life of a Moslem state: the sacred and fixed canon law of an Arab state is extended to every European. And this in turn, has reacted on the status of the non-Moslem subject races, and has come to be the indirect but chief support on which they lean. Through it, an element has developed which makes it practically impossible for a Moslem state to introduce legal changes even remotely affecting its non-Moslem population, alien or subject, without the consent of the European empires. Any change may be upset by their refusal to accept it as incommis- patible with the capitulations and conventions. The embassies have thus, as interpreters of a part, at least, of the constitution, come to hold a position remarkably, if absurdly, like that of the Supreme Court of the United States (see Young, Corps de droit Ottoman, passim).

2. Mahomedan had long been known in Arabia at the time of the Prophet. Whether Hebrews settled in Arabia as early as the time of David (cf. R. Dozy, Die Isroeliten zu Mecca, Leipzig, 1864), or not, is of little importance here as Judaism cannot be said to have existed until the end of the 6th century B.C. The Seleucid persecutions and the political troubles that ended with the fall of Jerusalem (A.D. 70) probably sent many Jews to Arabia. In the 4th and 6th centuries the history of south Arabia and of Nejran is largely that of the rise and fall of the Himyarite and the Ophirite states. Jews possessed Temâa, Khatab, Yathrib (Medina), Fadak, and other smaller settlements. In these they lived as self-contained communities, not seeking to proselytize but working at their trades, especially concerned with money and jewelry. Mahomet seems as have expected their help in his proclamation of monotheism, and his first qibla was Jerusalem. It was only when they refused to accept him as prophet that he turned in anger against them. They had, however, supplied him with much material from the Old Testament, and his followers later collected the material that came from the Eastern Church and probably to a large extent through Monophysite and Nestorian sects. Tradition says that Mahomet heard Christian preaching at the fair of Uzaq, and he himself participated in the argument of the sects. Other Gospel stories derived apparently from uncanonical works, such as the Gospel of the Nativity, occur in the Koran. The asceticism of the monks attracted his admiration. A mistaken notion of the Thirteenth Omeiyad caliph was that the Koran was written in the earliest times were called by the heathen Arabs, Sabians (q.v.), this being the name of a semi-Christian sect. In the time of the Omeyyads Christianity led to some of the earliest theological sects of Islam (see below).

3. Zoroastrianism was known to the Arab tribes in the north-east, but does not seem to have exercised any influence in Mecca or Medina except indirectly through Judaism in itsangelology. As soon, however, as the armies of Islam conquered Mesopotamia it began to penetrate the thought and practices of Islam (see below).

Sources of Authority.--Islam, as we are said, is founded on: (1) the Koran; (2) the tradition or rather the sunna (manner of life of Mahomet) contained in the tradition (Hadîth); (3) îmâma (the universal agreement); (4) qiyâs (analogy).

1. The Koran (properly Qur'an from qara'a to collect, or to read, recite) is the copy of an uncreated original preserved by God (see below), sent down from the seventh heaven to Gabriel in the first heaven, and revealed to Mahomet in sections as occasion required. These revelations were recited by the Prophet and in many cases written down at once, though from i. 100 it would seem that this was not always the case. God is the speaker throughout the revelations. It seems probable that the whole Koran was written in Mahomet's lifetime, but not brought together as a whole or arranged in order.

As it exists now the Koran consists of 114 chapters called suras (from sura, a row of bricks in a wall, a degree or step). The first is the sura of al-Fatihah, which occupies the place of the Lord's Prayer in Christianity. The others are arranged generally in order of length, the longest coming first, the shortest (often the earliest in date) coming at the end. Certain groups, however, indicated by initials, are kept together, and several of the suras are kept together from the time of the Prophet. At the head of each sura is a title, the place of its origin (Mecca or Medina) and the number of its verses (qulā' or sūrāj) together with the formula. In the name of God the Merciful, the Merciful, the clemency of the Lord (Allâh 'alîm, 'arham, rahmat). The whole text is divided into 60 sections (ajâbîn) or 30 divisions (ajâbîn), each subdivided into a number of prostrations (rū'kâ or sâjâ). The origin of the collected and written Koran is due to Omeiyad caliphate. At the secretory of Mahomet, was commissioned to collect all he could find of the revelation. His work seems to have been simply that of a collector. He seems to have done his work thoroughly and made a copy of the whole for Abu Bekr. The collection was thus chiefly a private matter, and this copy passed after Abu Bekr's death into the hands of Omar, and after his death to Hāfa, daughter of Omar, a widow of Mahomet. In the caliphate of Othman it was discovered that there were serious differences between the readings of the Koran possessed by the Syrian monks and those of the Eastern soldiers, and Othman was urged to have a copy prepared which should be authoritative for the Moslem world. He appointed Zaid ibn Thabit and three members of the tribe of Koreish (Qurashi) to the task of preparing a text which was to be carefully preserving Koreshe forms of words. How far the text was amended by the help of other copies is doubtful; in any case the mode of procedure was undoubtedly very conservative. The four similar manuscripts were the texts from the collections of Uby ibn Kâb and of Idris Mas'ûd were, however, known to later commentators. The only variants after the time of Othman were owing to different ways of pronouncing the consonantal text. These are usually of little importance for the meaning. As the text is now always voweled, variations are found in the vowels of different copies, and the opinions of seven leading "readers" are regarded as worthy of respect by commentators (see Th. Nöldeke, Geschichte der Queris., p. 279 seqq.); Gottingen, 1860, and Ahmad Bekr's collection is enable one to establish with more or less certainty the relative chronological order of the suras in the Koran, at any rate so far as to place them in the first or second Meccan period or that of Medina. The form of the utterances published in Suras 2, 36, 39, 61, 72, 82, 87, 103, 105, 107, 109, to 114, are usually written in the surj form (see Arabic Literature). The expressions used also help; thus the "O ye people" of the Meccan period is replaced in the Medina suras by "O ye who believe." The oaths in the first Meccan and Medina periods were the "Omeiyad oath" (in his Mohammed Zöeeri Teil. Einleitung in den Koran. System der koranischen Theologie, Münch., 1859), have arranged the suras as follows:—

Order of Suras in Koran.

* Mecca. 1st to 5th yr. (a). 96. 74. 111. 106. 108. 104. 107. 102. 105. 92. 90. 94. 93. 97. 86. 91. 80. 76. 87. 95. 103. 85. 73. 101. 107. 102. 81. 83. 84. 100. 79. 77. 78. 88. 75. 83. 69. 51. 52. 56. 79. 53. 112. 109. 113. 114. 11.

5th and 6th yr. (b). 54. 37. 71. 76. 44. 50. 20. 26. 15. 19. 38. 36. 43. 72. 67. 23. 21. 17. 27. 10. 47.

7th yr. to Flight (c). 34. 26. 11. 96. 41. 52. 1. 14. 54. 39. 29. 31. 42. 10. 34. 35. 7. 46. 6. 17.

Medina. 2. 98. 64. 8. 47. 43. 61. 57. 54. 69. 33. 64. 21. 58. 24. 48. 66. 66. 110. 49. 9. 3.

Grimme. 1. (In old surj form) 111. 107. 106. 104. 103. 102. 101. 100. 99. 108. 96. 95. 94. 93. 92. 91. 90. 89. 88. 87. 86. 85. 84. 83. 82. 81. 80. 79. 78. 77. 76. 75. 74. 73. 70. 69. 68. 114. 113. 56. 55. 54. 53. 52. 51. 50. 15. 12. 14.

2. In loosen surj form) 46. 72. 45. 44. 41. 97. 40. 39. 38. 37. 36. 34. 32. 31. 67. 60. 29. 28. 27. 26. 25. 20. 24. 23. 21. 19. 14. 12. 17. 16. 15. 12. 11. 10. 2. 6. 98. 112. 109.

From the Flight to 2. 62. 55. 54. 106--108--47 and some interpolations.

Mecca: In Meccan surras.

From Badr to Ohod 8. 24. 59.

From Gayd to Siddah 3. 57. 56. 61. 60. 58. 53. 63. 49.

Meditation. 110. 48. 54. 64. 91. 44. 41.

After capture of Mecca. 9a-124.

On the supposition that the arrangements given above are at any rate approximately correct, it is possible to trace a certain development in the teaching of the Koran on some of the chief dogmas. It must, however, be borne in mind that orthodox Islam recognizes the Koran as the work not of Mahomet but of God. Yet Moslem theologians recognize that some revelations are inconsistent with others, and so have developed the doctrine of nástûk and mansûk ("abrogating" and "abrogated"), whereby it is taught that in certain definite cases a later revelation supersedes an earlier. A critical study of the Koran shows in the earlier revelations the marks of a reflective mind trained under the influence of Arabian education

1 Underlined = with interpolations.
and stirred by an acquaintance (somewhat imperfect) with Judaism and Christianity. The later revelations seem to be influenced by the now dominant position of the Prophet and a desire after the capture of Mecca to incorporate such heathen religious ceremonies as are national. God is one and universal from the beginning. His unity is emphasized as against the mistaken conception of the Christian Trinity. At first his might is taught by the name Rabb (Lord) which is generally used with an attribute as "the highest Lord," "Lord of the worlds," "Lord of men," "Lord of heaven and earth," "Lord of the East and West," or "our Lord." Then he is identified with the god Allah (see above) and the first part of the later Moslem creed is announced—la ilaha illa-illaah, "there is no god but Allah." But every act of creation is a proof not only of God's power but also of his benevolence (xiv. 37), and so he becomes known as ar-Rahmān, "the Compassionate." The attributes of God may all be arranged in the three classes of his power, unity and goodness. They are expressed by the ninety-nine "beautiful names" applied to him in the Koran (see E. H. Palmer, The Quran in "Sacred Books of the East," vol. vii. Oxford, 1880). In the Medine period of life the nature of God is not so clear, and the description of it varies according to the moods of the Prophet.

Beside God are two other uncreated beings: (1) the original of the Koran, the "mother of the Book" (xiii. 3) on a "preserved tablet" (laух mahfūṣ) (xxxv. 22), in accordance with which God acts, and (2) the throne (kursi) (ll. 256). When the heavens are created, God sits on his throne in the seventh heaven; around him are angels, pure, sexless beings, some of whom bear the throne, while some are engaged in praising him continually. They are also his messengers and are sent to fight with the believers against the heathen. Some are the guardian angels of men, others are the watchmen of hell. Mediate beings between God and man are the "word" (amr) and from it the "spirit" (raḥ) or "holy spirit" (raḥ ul-qudr). Another manifestation of God to the believers only is the "glory" (sakina).

God created the world in six days according to the plan of the Book. Each new life was created by God's breathing into it a soul. The duality of soul and body is maintained.

Cosmology. In each man is a good and a bad impulse. The bad impulse which was latent in Adam was roused to action by Satan (Iblis). Adam by his fall lost the grace of God, which was restored to him solely by the gracious choice of God. Between men and angels in their nature are the genii (jinn) male and female, inhabitants of desert places, created from smokeless fire. They had been accustomed to spy round heaven, but in Mahomet's time could learn no more of its secrets. Some of them were converted by the Prophet's teaching. Lowest of creation in his estate is Satan (Shaitān), who was an angel but was expelled from heaven because he refused to worship Adam at his Lord's command. God has revealed himself to man by (1) writing (kitāb), and (2) prophets. As he had given to the Jews the Law (Taurad) and to the Christians the Gospel (Injīl) so he revealed to Mahomet the Koran (Qurān, known also by other names, e.g. al-Furqān, al-Taurāt, &c.), each single revelation being called an uzā. With his revelation God has also sent an apostle or prophet to each people. Several of these are mentioned in the Koran, Moses the prophet of the Jews, Jesus (Isa) that of the Christians. Mahomet is not only the apostle of the Moslems but the "seal of the prophets," i.e. the final member of the class. His mission at first was to warn men of imminent judgment. Later he became more of a teacher. At first he seems to have relied for the salvation of men on his natural faculties, but later announced the doctrine of God's election. The ethics of the Koran are based on belief (ismād) and good works, the latter alone occurring in the early Meccan suras. Fear of the judgment of God was a motive of action; this is followed by repentance and turning to God. A complete surrender to God's will (islām) is the necessary condition of religious life and is expressed in the phrase so common in everyday speech among the Moslems—inshā'Allah, "if God will." God has full power to overlook evil deeds if he will. Unbelievers can acquire no merit, however moral their actions.

A short account of the chief ethical requirements of the Koran is given in xvi. 23-40:—

"Put not God with other gods, or thou wilt sit despised and forsaken. Thy Lord has dereed that ye shall not serve other than Him; and kindness to one's parents, whether one or both of them reach old age with thee, and say not to them, 'Fie!' and do not grumble at them, but speak to them a generous speech. And lower to the earth thy voice for fear that they should have compassion on them as they brought me up when I was little!' Your Lord knows best what is in your souls if ye be righteous, and, verily, He is forgiving unto those who come back penitent.

"And if thou sayest to a man, thou wilt strike him with the poor son of the road; and waste not wastefully, for the wasteful were ever the devil's brothers, and the devil is ever ungrateful to his Lord.

"And if thou dost turn away from them to seek after mercy from thy Lord, then lo! thy Lord is Forgiving to such as turn back to Him in repentance."

"Make not thy hand fettered to thy neck, nor yet spread it out quite open, lest thou shouldst have to sit down blamed and straightened in means. Verily, thy Lord spreads out provision to whomsoever He will. He does out. Verily, He is ever well aware of and sees His servants.

"And slay not your children for fear of poverty; we will provide for them; beware! for to slay them is ever a great sin.

"And draw not near to fornication; verily, it is ever an abomination. And evil is the thing that ye are so fond of."

"And slay not the soul that God has forbidden you, except for just cause; for he who slays unjustly we have given his next of kin authority; yet let him not exceed in slaying; verily, he is ever helped."

"And remember that God's help is better and a fairer determination."

"And do not pursue of that which thou hast no knowledge; verily, the hearing, the sight and the heart, all of these shall be enquired of."

"And walk not on the earth proudly; verily, thou canst not clear the earth, and thou shalt not reach the mountains in height."

"All this is ever evil in the sight of your Lord and abhorred." (E. H. Palmer's translation.)

The eschatology of the Koran is especially prominent in its earlier parts. The resurrection, last judgment, paradise and hell are all described. At death the body again becomes earth, while the soul sinks into a state of sleep or unconsciousness. At a time decreed, known as "the hour" (as-Sa'a), "the day of resurrection" (yaum ul-qiyāmā), "day of judgment" (yaum-ul-dīn), &c., an angel will call or will sound a trumpet, the earth will be broken up, and the soul will rejoin the body. God will appear on his throne with angels. The great book will be opened, and a list of his deeds will be given to every man, to the good in his right hand, to the evil in his left (sura 69). A balance will be used to weigh the deeds. The jinn will testify against the idolaters. The righteous will then obtain eternal peace and joy in the garden (al-jannah) and the wicked will be cast into the fiery ditch (Jannahum), where pains of body and of soul are united.

2. The Tradition.—The revelation of God is twofold—in a writing and by a prophet. The former was contained in the Koran, the latter was known from the actions of Mahomet in the different circumstances of life. The manner of life of the Prophet (sunnah) was contained in the tradition (al-hadith). The information required was at first naturally obtained by word of mouth from the companions and helpers of Mahomet. These in turn bequeathed their information to their younger companions, who quoted traditions and gave decisions in their names.

For long these traditions circulated orally, the authority of each depending on the person who first gave it and the reliability of the chain (ismād) of men who had passed it on from him. At first this tradition was regarded as explanatory of, or at the most supplementary to, the text of the Koran. Or, rather, the Koran was pointed to the Jews as having two law-books—the Taurāt and the Mishna—while Islam had only one—the Koran. But opinion changed, the value of tradition as an independent revelation came to be more highly esteemed until at last it was seriously discussed whether a tradition might not abrogate a passage of the Koran with which it varied. The writing of traditions was at first strongly discouraged, and for more than a century the stories of the Prophet's conduct passed from mouth to mouth. Had all the narrators been pious men, this might have been tolerable, but this was not the case. The Omayyad dynasty was not a pious one. Men who were not religious but wished to appear so invented
420 MAHOMMEDAN RELIGION

traditions to justify their manner of life. The sectarians did not hesitate to adopt the same means of spreading their own teaching. Many Moslem writers testify to the fact that forged traditions were circulated, and that religious opinion was confused thereby. The need for some sort of authoritative code of doctrine and meaning and ceremonial requirements was felt by the pedants and men of the book, e.g., Omar II. (717-720), who is said to have ordered Ibn Shihab uz-Zuhri to make such a collection. Of this work, if it was carried out, we know nothing further. It was, however, a man born during this reign that the first steps towards a systematic collection of traditional material by the Malik ibn Anas (q.v.). Yet this work is not a book of tradition in the religious sense. It is really a corpus juris and not a complete one. The object of Malik was simply to record every tradition that had been used to explain or justify the doctrines and practices of the Orthodox. The method on which the Maliki school is based, unfortunately, of the different parts of religious and life practice was first undertaken in the 3rd century of Islam (a.d. 815-912). In this century the six collections of tradition known as the six bookshelves were made. By this time an immense number of traditions was in circulation. Bukhari in the course of sixteen years' journeying through Moslem lands collected 600,000, and of these included 7285 (or, allowing for repetitions, 4000) in his work. The six collections of tradition received by the Sunnites as authoritative are:

(i) the Kitab ul-Jami' of Bukhari (q.e.) (810-870). This is the most respected throughout the Moslem world and most carefully compiled (ed. L. Krael and T. W. Juyboll, Leiden, 1862-1862) and it is used frequently in the East; also with many commentaries. (French translation by O. Houdas and W. Marcas, Paris, 1903 seq.) (ii) the Sahih of Muslim (817-857) with an introduction on the science of tradition (ed. Calcutta, 1889, etc.). (iii) the Kitab al-Masalik of Abul-Faraj (ed. Calcutta, 1863, Lucknow, 1888, Delhi, 1890). (iv) the Kitab al-Jami' of Tirmidhi (q.e.). (v) the Kitab al-Sunan of Nasai (830-915) (ed. Cairo, 1894). (vi) the Kitab as-Sunan of Ibn Majah (824-866) (ed. Delhi, 1865 and 1889). The last four are not so much venerated as the first two.

3. Ijma is the universal consent which is held to justify practices or beliefs, although they are not warranted by the Koran or tradition, and may be inconsistent with the apparent teaching of one or both of these. These beliefs and practices, which had often come from the pre-Islamic customs of those who had become believers, seem to have escaped notice until the Abbasid period. They were too deeply rooted in the lives of men to be abolished. It became necessary either to find a tradition to abrogate the earlier forbidding one, or to acknowledge that ijma is higher than the tradition. The former expedient was resorted to by some later theologians (e.g. Nawawi) by a fiction that such a tradition existed though it was not found now in writing. But in earlier times some (as Ibn Qutab) had adopted the former alternative, saying that the truth can be derived much earlier from the ijma than from the tradition, because it is not open to the same corruptions of corruption in its transmission as the latter. Tradition itself was found to confirm this view, for the Prophet is related to have said, "My people do not agree in any thing but the ijma." But ijma is itself has been used in different senses: (i) The ijma of Medina was used to indicate the authority coming from the practices of the people of Medinna (see below). (ii) The ijma of the whole community of Moslems is that most commonly recognized. It was used to support legality to the Abbasid dynasty. By it the six books of tradition mentioned above are recognized as authoritative, and it is the justification of the conception of Mahomet as superhuman, (iii) Some of the most thoughtful theologians recognize only the ijma of the former rulers of Islam, when the tradition is not restricted by the orthodox to the first few generations after Mahomet, while the Shiites allow the existence of such up to the present time.

4. The fourth basis of Islam is giyas, i.e. analogy. It is that process by which a belief or practice is justified on the ground of something similar but not identical in the Koran, the tradition or ijma. Originally it seems to have been instituted as a check upon the use of private opinion (ra'i) in the teaching of doctrine. The extent to which it may be used is a subject of much discussion among theologians. Some would apply it only to a "material similarity," others to similarity of motive or cause as well.

Worship and Ritual.—The acts of worship required by Islam are in number: (i) the recital of the creed; (ii) observance of the five daily prayers; (iii) the fast in the month of Ramadhan; (iv) giving of the legal alms; (v) the pilgrimage to Mecca.

i. The creed is belief—"I lailla illa-lahhu, Muhammad rasul allah," there is no god but God (Allah), Mahomet is the apostle of God." It is required that this shall be recited at least once in a lifetime aloud, correctly, with full understanding of its signification and faithfulness in its truth. It is to be professed without hesitation at any time until death.

ii. Every man who professes Islam is required in ordinary life to pray five times in each day. In the Koran these prayers are commanded, though not strictly enforced. They are a worship of God, the evening hearkened to, and when ye rise in the morning, and unto Him be praise in Heaven and earth; and in the evening and when ye rest at noon (xxx. 16-17), but commentators say that in the morning prayers, and after sunset, this work, of the recital of the creed, is made. But the soundness of this view, whether the recital of the creed be made or not, is thrown into doubt. It is required that the recitals may be delayed without impairing their validity. Prayer is preceded by ablutions (wudu), and afterwards certain physical positions are prescribed for each part of the worship; these vary slightly in the four orthodox schools (see below). On a journey, in time of war or in other special circumstances, the set form of the observance is often suspended. Besides these private prayers, there is the prayer of the assembly, which is observed on a Friday (yasum ul-jami,' the day of assembly') in a mosque, and is usually accompanied by an address or declamation (khutba). It commences with the recital of the creed. Whether public prayer is prescribed for certain occasions, as on the eclipse of the sun or the moon, &c. Among the Sufis special attention is given to informal prayer, consisting chiefly in the continual repetition of the name of God (tasbih). This is still a characteristic of some of the dervish (q.e.) communities.

iii. The command to fast begins with the words, "O ye who believe! is prescribed for you the fast, as it was prescribed for those before you," and was expressed in the phrase before fast the day of atonement, but more probably refers to the fast of thirty-six days observed by the Eastern Christians. In the passage of the Koran referred to (ii. 179-181) Moslems are required to fast during the hottest month of the year, but in the Abbasid caliphate, but if one is on a journey or sick he may fast another number of days," and if he is able to fast and does not, "he may remit it by feeding a poor man," but if he is able to fast and does not for the fast, is better for you." This fast is observed in the month of Ramadhan, which is defined as "the month in which the Koran first descended," and is the month during which the faithful Moslem makes his pilgrimage to Mecca. If a Moslem be not able to attend the pilgrimage, provided he has means to make the journey, he may send his ablation to a person (wakil) to satisfy the law for him. The pilgrimage is paid for by the fiqah and by him who undertakes its performance.

iv. Alms are of two kinds: (1) the legal and determined (sadaqat), and (2) voluntary (sadaqat). The former were given in cattle, grain, fruit, money, and the like. They were usually paid to the poor, and were used for the building of mosques and similar religious purposes. At the present time the carrying out of the devotion is left to the conscience of the believers, who pay the alms to any needy fellow Moslem in the form of a charity. A Moslem is under no compulsion to make public an unmade charity (see C. M. Doughty, Arabia deserta, i. 446, ii. 278, Cambridge, 1888).

v. The fifth religious duty of the Moslem is the pilgrimage (hajj) to Mecca which should be performed at least once in a lifetime. If he is "able," that is, if he can provide or obtain the means to support himself on pilgrimage and his family during his absence, and if he is physically capable. The pilgrimage is made at the end of the month Dhu'l-Hijja. For the arrangements for the journey from various countries to Mecca see CARAVAN. When the pilgrim arrives within five or six miles of the holy city he puts off his ordinary dress and dons ceremonial trappings. He is then permitted to wear the four white garments which dress the form of the pilgrim (the tārām), who goes without head-covering or boots or shoes. He must not shave at all, or trim the nails, or anoint the head during the ceremonial period. The chief parts of the ceremonial are the visit to the sacred mosque masjid al-gharām), the kissing of the black stone, the compassing of
MAHOMMEDAN RELIGION

421

the Ka`ba (the `Tawf`) seven times, three times running, four times slowly, the visit to the Ma`qar `Ibrahim, the ascent of Mount Safa
and running from it to Mount Marwa seven times, the run to Mount
`Arafat, hearing a sermon, and going to Muzdalifah, where he stays the
night and cease of the pilgrimage. He then goes back to Mecca, on the great
feast day, and the offering of sacrifice there (for the localities see
Mecca). After the accomplishment of these ceremonies the ordinary
dress is resumed, the pilgrimage is finished, but the pilgrim usually
remains in Mecca, especially in Medina, to pay his respects to the tomb of
Mahomet. Beside the hajj (great pilgrimage) Islam also recognizes the merit of the
`umra (or lesser pilgrimage), i.e. a religious visit to Mecca at any time accompanied by most of the
components of the hajj.
The ceremonies of the hajj have been described by several European
travellers who have witnessed them, such as J. L. Burckhardt in
1814, Sir Richard Burton in 1853 (see bibliography to Mecca). A
concise account of the ceremonies in the Koran has been given in T.
Stewart Mosleim (3rd ed., London, 1894). Details in vol. i. of Bukhârî's
traditions (Houdas and Marcâis's French translation, i. 493-567).
The Development of Islam.—The battle of Siffin (657) between
`Ali and Moawiyah was the occasion of the first breach in the
unity of Islam, and the results remain to this day. The occasion
was in the first case political, but politics were at that time too
intimately connected with religion to be considered apart from it.
After the battle (see CALLIPATE) `Ali was practically compelled
to submit his claims to arbitration, whereupon a number of his
supporters broke away from him, saying that there should have
been no appeal save to the Book of God. These men were for
the most part country Arabs, and, inspired by the free spirit
of the desert, were democratic, claiming that the caliph should be
elected by the whole community from any family (and not from
the Kureish alone), and that the caliph might be deposed for sin.
A few extremists were republicans and would do without a
caliph altogether. The whole party was known as the Kharjites (Kharîjyya or Kharwâri). The Moslems who disagreed with
them were regarded by them as renegades and were to be put to
death. They were soon divided into extremists and moderates.
The former put to death the children of unbelievers and refused to
hold intercourse in daily life with unbelievers. The moderates,
who came to be known as Ibadites (from their leader `Abdallah
ibn `Abd), would allow the children of unbelievers to grow up,
and would then deal with them according to their choice. In
ordinary life they would mix with all men, but marriage with
other Moslems outside their own ranks was forbidden. These still
remain in Oman, parts of Algeria and East Africa.
Another party, consisting mainly of city Arabs infected with
Persian ideas as to the divinity of the ruler, clung to `Ali with
inconvenient affection. They regarded `Ali and his descendants
as the only legitimate caliphs, and came to be known as Shi`ites (g.v.).
They remain to-day the largest part of Islam outside
orthodoxy. During the Omayyad caliphate (661-750) there
were three centres of religious thought and influence; students
and teachers often passed from one to the other, thus making
universal the teachings which in their origin were due to local
circumstances. These centres were Damascus (the seat of the
caliphate), Medina and the East (Irak, &c.). In Damascus the
religious thought was essentially uncreative. The Omayyads were
only considered as Jews and Christians in the eyes of many of Islam.
The early Omayyads were distinguished for their striving after
dominion (mudâk). Instead of attempting to propagate Islam,
they tolerated other religions and favoured Christians who were
distinguished as poets (e.g. Akhtal) or officials (John of Damascus),
or men likely to be of use to them in any way. The doctrines of
Christianity began to influence even serious Moslems and to
affect their way of viewing Moslem belief. John of Damascus
(d. before 767), the Greek theologian, and his pupil, Theodorus
Abugara (d. 826), have written controversial works on Islam,
from which it seems probable that disputations on subjects per-
taining to religion were held between Christians and Moslems.
Two schools of heretical Moslem sects arose under these influ-
ces—that of the Murjites and that of the Qadarites. The
Murjites ("postponers") were so called because they postponed
the judgment of human actions until the Day of Judgment. In
politics they accepted the Omayyads as de facto rulers, since they
were Moslems, and left the judgment of their actions to God.
As theologians they taught that religion consists in belief (iman) in
the unity of God and in his apostle, and in that alone, conse-
cquently no one who held this faith would perish eternally, though
he had been a sinner. This was opposed to the Kharijite
document that the unrepentant sinner would perish eternally,
even though he had professed Islam.
The Qadarites were concerned with the doctrine of pre-
destination and free-will. So long as Moslems were fighting the
battles of Islam they naturally paid most attention to those
revelations which laid stress on the absolute determination of a
man's destiny by God. They fought with great bravery because
they believed that God had foreordained their death or life and
they could not escape His will. In the quieter realm of town
and court life and in their disputations with Christians they were
called upon to reconcile this belief with the appeals made in the
Koran to man's own self-determination to good, to courage.
&c. Mahomet was not a systematic theologian and had done nothing
to help them. The Qadarites declared that man had power over
his own actions. But the teaching of predestination had gained
too great a hold on Moslems to be thus displaced. The teaching of
the Qadarites was held to be heresy, and one of its first pro-
fessors, Ma`bad ul-Juhâni, was put to death in 699.4 During
this period Medina was the home of tradition. Those who had
been in closest relation with the Prophet dwelt there. The very
people of the city derived a certain splendour and authority
from the fact that Mahomet had lived and was buried there.
Free thought in religion had little chance of arising, less of
expressing itself, in the holy city. But the Koran was diligently
studied, traditions were collected (and invented) though not yet
written in books, and innovation (bid`a) was resolutely avoided.
At the same time it really did contribute a new element to
religious practice, for the custom (ijma', see above) of Medina
gained a certain authority even in Syria and the East.
In the East, on the other hand, there was more mental activity,
and the religious teachers who came from Medina had to be pre-
mature to meet with many questions. The wits of the Moslems
were sharpened by daily contact with Christians, Buddhists,
Manichaeans and Zoroastrians. Hasan ul-Basri (g.v.), who has
been claimed as one of the first mystics, also as one of the first
systematic theologians of Islam, was remarkable alike for his
personal piety and his orthodoxy. Yet it was among his pupils
that the great rationalist movement originated. Its founder was
Wâsîl ibn `Atâ, who separated himself (whence his followers
were called Mutazilites, strictly Mu`tazilites, "Separatists"
from his teacher and founded a school which became numerous
and influential. The Mu`tazilites objected to the attributes of
God being considered in any way as entities besides God; they
explained away the anthropomorphisms used in speaking of the
deity; they regarded the Koran as created, and as a product of
Mahomet writing under the divine influence. Briefly, they
asserted the supremacy of reason (aql) as distinct from faith
received by assertion (nagî). They also called themselves "the
people of justice and unity" (Ahl ul-`adl wa-t-tauhid). Such a
notion has not been naturally found rather with the thinking
men than with the uneducated multitude, and was thought of
many vicissitudes. At the time of its appearance and until the
reign of Ma'mûn its adherents were pursued as heretics. After
discussions among the theologians Ma'mûn took the decided
step of proclaiming that the Koran was created, and that a belief
in this dogma was necessary. Other Mu`tazilite doctrines
were proclaimed later. Mu`tazilites were appointed to official
posts, and an inquisition (mi`mas) was appointed to enforce belief in
their doctrines. This movement was strongly opposed by the orthodox
and especially by Ahmad ibn Hanbal (g.v.). By him the founding
of theology on reason was rejected, and he suffered persecution
for his faith (see W. N. Paton, Ahmed ibn Hanbal and the Mi`ma,
Leiden, 1897). Mu`tazilism retained its sway until 849, when
the caliph Mutasawakkil again declared the Koran uncreate and
restored orthodoxy. It was during the early years of the Abbasid

4 For the doctrines of these two sects see Shahrastâni's Book of
Sects, and for the Qadarites, A. de Vlieger's Kitâb ul-Qadr, matériaux
pour servir à l'étude de la doctrine du prédestination dans la théologie
musulmane (Leiden, 1903).
rule that the four legal schools of Abû Hanîfa (d. 767), Malik ibn Anas (d. 795), ash-Shâhâb (d. 819) and Ibn Hanbal (d. 855) came into existence (see MAHOMMEDAN LAW). As the bases of religion and law were the same, so the methods applied in the treatment of the one affected the other. Abû Hanîfa depended little on tradition, but referred back to the Koran, making use of individual opinion (ra'y) as controlled by analogy (qiyás) with a written ordinance. Malik ibn Anas supplemented the Koran and Sunna by customary law founded largely on the custom (ijma') of Medina, and by what he conceived to be for the public good (isti'âbah). Shaî'î recognized tradition as equal to the Koran, and even as being able to supersede its ordinances, while he also recognized the universal custom (ijma') of the Moslem world as divine and binding. His four bases of religion—Koran, sunna, qiyas and ijma'—have been generally accepted in Islam (see above). Ibn Hanbal's position has already been mentioned. All these four schools are reckoned orthodox, and all orthodox Moslems belong to one or another of them. Another teacher of this time, who founded a school which did not succeed in being recognized as orthodox, was Da'îd az-Zâhîrî. Trained as a Shaî'î, he became too strict for the schools, rejected analogy, restricted ijma' to the agreement or custom of the companions of Mahomet, and accepted the whole of the Koran and tradition in the most literal and external sense. His followers were called Zâhîrites (i.e. externalists). After Ash'ârî's time these principles were applied to theology by Ibn Hazm (q.v.) see I. Goldziher, *Die Zâhîrîen, ihr Lehrsystem und ihre Geschichte* (Leipzig, 1884).

Before turning to the reform of Ash'ârî and the introduction into orthodox theology of scholastic philosophy it is necessary to notice another phase of religious life which became the common property of orthodox and heretics. This was the introduction of asceticism in religious practice and of mysticism in religious thought. Sufism (q.v.), which combined these two, is rightly not counted among the sects of Islam. Asceticism seems to have won a certain amount of approval from Mahomet himself, who much respected the Christian monks. The attention paid in early Islam to the joys and punishments of the future life led to self-denial and simple living in this world. An Arabian writer, speaking of the simplicity of manners of the first four caliphs, says that their affairs were conducted with more consideration of the future life than of this world. Many Moslems went even farther than these caliphs, and gave up all concern as far as possible with the affairs of this world and lived in poverty, in wanderings or in retirement (see Dervish). For the historical development of this movement, with its accompanying mysticism, see Sufism. Ash'ârî (d. before 942) was for forty years a Mu'tazilite, then became orthodox (see Ash'ârî), and at once applied rational methods for the support and interpretation of the orthodox faith. Before him, reason had not been allowed any scope in orthodox theology. He was not the first to use it; some teachers (as al-Junaidî) had employed it in teaching, but only in secret and for the few. The methods of scholastic philosophy were now introduced into Moslem theology. The chief characteristic of his religious teaching was the adoption of the *wa 'adha* between materialistic grossness and the ideas of pure speculative philosophy. Thus he taught, as to the attributes of God, that they exist, but are not to be compared with human attributes; as to His visibility, that He can be seen but not the limitations of human sight. As to the great question of free will, he would not, in principle, admit the power but asserted his responsibility. So he passed in review the doctrines of God, faith, the Koran, sin, intercession, &c., and for the first time in the history of Islam produced a systematic theology. The teaching of Ash'ârî was taken up and propagated by the Buyids soon after his death, and was developed and perfected by Abû Bekr ul-Baqîlî, the Cadi (d. 1012), but up to the middle of the 5th century of Islam (c. A.D. 1058) was respected elsewhere and confounded with Mu'tazilism. The Ash'ârite al-Juwayñî (known as 'Imâm al-Haramayn) was persecuted under Toghurl Beg (c. 1053) and exiled, but was restored under Alp Arslan by the vizier Niẓâm ul-Mulk, who founded an Ash'ârite college (the Niẓâmîyya). In the West, Ibn Hazm (q.v.) fiercely opposed the system, but Ghazâlî defended its orthodoxy in the East, and it spread from Persia to Syria and Egypt under the Ayyûbies and Mamelukes and thence to the Almohades in Africa under Ibn Tumart (1130). It remains the predominating school to the present day, its only serious rival being the theological system of the Mu'tazilites. Abû Malik ibn al-Hajar (d. 942), whose creed is represented as that of an-Nasawî is still followed by the Turks. Since the 13th century no great theological movement has been made in Islam. The quiet of religious life has twice been broken, once by Wahbâbîm (q.v.) in Arabia, once by Bâbîm (q.v.) in Persia.

**The sects**

According to an early tradition Mahomet said that Islam would be divided into seventy-three parties (sects), of which seventy-two would perish and one would be saved. The orthodox Arabian writers on heretical sects of Islam feel compelled by this tradition to make up their number to seventy-two, and, as different writers adopt different divisions or are familiar with different parties, the names of sects amount to some hundreds. Each writer, however, adopts certain main classes under which he attempts to group the others. Abû Mu'tî Makhâlî at the beginning of the 19th century in his "Refutation" (MS. in Bodleian Library) has six such chief classes: Harâritîs (i.e. Khârîjîs), Râdîdîs (i.e. Shi'îtes), Qadâritâs, Jâbâritâs, Jâmhîrîs, and Murjîtîs. Ibn Hazm (q.v.) adopts four classes; Mu'tazîlîs (Motazîlîs), Mûjîrîs, Shi'îtes, and Khârîjîs. Shahraštânî (q.v.) complains of the want of system in earlier writers, and suggests as bases of classification the position of parties with regard to the doctrines as to (1) the divine attributes, (2) predetermination and free-will (3) promises and threats, faith and incor, (4) revelation, reason, the imâmât. In one part of his preface he gives as the chief parties the Qadârîs, Shi'îtes, Khârîjîs and Shi'îtes, proposing to divide these classes according to leaders who agreed with the main doctrines of their class but differed in some points. In another place he mentions four opposite pairs of sects: (1) the Qâdârîs with their doctrine of free-will, and the Jâbârîs, who are necessitarian; (2) the Shi'îtes, who maintain the eternal nature of the attributes of God, and the Mu'tazîlîs, who deny it; (3) the Murjîtîs, who postpone judgment of actions until the Last Day, and the Wa'îdîs, who condemn in this life; (4) the Khârîjîs, who consider the caliphate a human institution, and the Shi'îtes, who defy their ruler. In his detailed description of the sects Shahraštânî arranged them under the headings: Mu'tazîlîs, Jâbârîs, Shi'îtes, Khârîjîs, Murjîtîs and Shi'îtes. About the same time as Shahraštânî two other Arabian writers wrote on the sects—Tâhir ul-Îsairâni (d. 1078), whose MS. is in the Berlin library, and Abû ul-Qâdir âl-ul-Jâlînî (1078–1166) in his *Kûlûl-ul-Ghântîyya il Mü'lîl Îsâ al-Hâmmîyyâ* (Cairo, 1871). Both adopt as main classes Râdîdîs (or Shi'îtes), Qadârîs (or Mu'tazîlîs), Khârîjîs, Murjîtîs, Najârîtîs, I. Hittës, Jâbârîs, Mûjîrîs, to which Tâhir adds Bakîrîs, Kârâmîs, and a class including those sects which are not reckoned as Moslem though they have sprung from Islam. Jâlînî adds to the eight the Khâlîbîs. The following list is not a complete list of names of sects but is founded on that of Shahraštânî. Zâhîrites.—Shi'îtes of the Imâmî class, who ascribe the imâmât to 'Abdallah ul-A'fâbî, the son of Sâdîq. Ajâdîs.—Khârîjîs, followers of Ibn 'Ajjardâr, who agreed for the most part with the Norashîn, considered grave sins as equivalent to unbelief, but remained friendly with those who professed Islam but did not fight for it. They rejected *sura 7* as a false. Shahraštànî enumerates seven divisions of this sect.

1 For the origin and significance of this number see M. Steinschnei.

The names are given throughout in the anglicized form on the analogy of Shîites, which is recognized in common usage. The strict termination according to the scheme of transmutation adopted in this work (as below), considered grave sins as equivalent to unbelief, but remained friendly with those who professed Islam but did not fight for it. They rejected *sura 7* as a false. Shahraštànî enumerates seven divisions of this sect.
MAHOMMEDAN RELIGION

Akhnasites.—A section of the Tha‘alibiya not so strict in treatment of those who fear to fight for Islam.

Ash‘urites.—Followers of Ash‘ar (q.v.) who are counted by Shahhastan among the Shi’ites.

Arajites.—A division of the ‘Ajirite who agree with the Hamites except that they cease the lower classes for inaction when they are ignorant of the law.

Araqjites.—Kharjites who followed al’Araq in the days of Ibn Zubair. They held ‘Ali to be an unbeliever; those who did not fight were deemed unbelievers and were put to death and went to hell. Sin is unbelie.

Bashkamites.—Mut’azilites akin to the Jubbites.

Bashkites.—Kharjites, followers of Abu Baluha ul-Haitham, who was the third Imam of the Khalaf Walid. They asserted the necessity of knowledge for religion.

Baghites.—Shi’ites who followed Abu Ja‘far ul-Baqir, the fifth imam, and looked for his return.

Baddites.—Imamites also called because they believe that every external has an internal (bātīt), and every passage in the Koran has an allegoric meaning.

Bishrites.—Mut’azilites, followers of Bishr ibn Mu’tamir, one of the most learned men of his party. This teaching was called ‘‘invented’’ and was distinguished by his doctrine of ‘‘origination’’ (tawālīd).

Bundnites.—Kaisainites, followers of Bunun ibn Sim‘an un-Nahdī, who claimed that the imamate passed from Abu Hassim to himself and that he had also acquired the divine element of ‘‘Ali.‘‘

Budhites.—Nasriones, followers of ar-Nawā‘ al-’Abtar, who agreed with the Suleimantas (Sulainimantas) except that he suspended judgment as to whether Othman was a believer or not.

Darites.—Jabarites who empty God of his attributes, and assert that God is a being by himself, and who believe that God only one day of resurrection. The actions of man are ‘‘created’’ and acquired by him. A caliph need not be chosen from the Koresheh.

Dhāliites (Ghūla) are the extreme Shi‘ites (q.v.) in ascribing deity to the attributes and the supremacy of the body. They are divided into: (1) Making God resemble man, (2) ascribing change of mind to God, (3) looking for the return of the imam, (4) metempsychosis. They are divided by Shahhastan into ten classes.

Family.—Jabarites, followers of a man ibn Kufī, who say that faith consists of knowledge of God, his apostle, and the Koran in general not in detail, and that faith increases but is diminished.

‘Ibadites.—Hūyaites (below).

‘Ibadites.—Mut’azilites, followers of Fadl ibn ul-Hadathī, who agreed with the Hūyaites (below).

‘Ibadites.—Jubbais, followers of Ḥāṣal ibn abī-l-Miqdām, who distinguished between idolatry (shirk) and unbelief (kufr).

Jāmīites.—‘Ajīrīs, followers of Hamza ibn Adārak in Sijistan. They agreed with the Mainimantas, but condemned the children of unbelievers to hell.

Jārījītes.—‘Ilbādites, followers of Ḥaṣīb ibn abī-l-Miqdām, who were disowned by Shahhastan and able to hold their votes without being counted.

‘Iljītes.—Mut’azilites, agreed with the ‘Ijīiz, but added three heresies of their own: (1) the divinity of the Messiah, (2) metempsychosis, (3) the interpretation of all references to the vision of God as referring to the ‘‘first Reason’’ or ‘‘creative Reason.’’

Hāshimites.—A name given to two sects: (1) Mut’azilites, strong in their assertion of man’s free-will, even opposing the statement of the Koran. (2) Shi’ites of the extreme kind, who attributed to ‘‘body with particularities (measurements) and qualities.

Judaites.—See Hadijitas.

Hudhailites (Hodhailites).—Mut’azilites, followers of abū-l-Hudhal Ḥamdān, who was a leading teacher of his party and developed the principles of his teaching. Ten of his main doctrines are given by Shahhastan.

Jabites.—Kharjites of moderate tendencies (see above).

Jālīites.—Mut’azilites who put ‘‘All above Mahomet and blamed the latter, because he did not put the former end of the Imam.

Imāmites.—One of the chief divisions of the Shi‘ites (q.v.).

Imāmītis.—Mut’azilites agreeing with the Nūsairites except that they incline to speak of the imams’ participation in the prophetic office.

Isma‘īlites.—This name is applied to all who consider Isma‘īl ibn Ja‘far the last imam, some believing that he did not die but will return, others that at his death his son Mahomet became imam (see ‘‘INSA‘INS’’); it is also used as equivalent to the Bājtīrites.

Ish’āsharites.—Imāmītes who accept the twelve imams (see Shi‘ites).

Jabarites.—Those who deny all actions and power to act to man and ascribe all to God (see above).

Jafarites.—Imāmītes who carry the imāmate no farther than Ja‘far us-Sādiq.

Jahizites.—Mut’azilites, followers of the celebrated writer Jāhiz (q.v.), who indulged in philosophical speculations, believed in the eternity of matter, and was regarded as a naturalist (fabāri) rather than a theologian (al-‘adlī).

Jahmites.—Jabarites, followers of Jahm ibn Sa‘fīwān, who was put to death at Merv toward the close of the Omayyad period. He was extreme in his denial of the attributes of God. If he denied that the imamites who believed that Mahomet designated ‘‘All as imām, not by name but by his attributes, and that the Moslem sinned by not taking sufficient trouble to recognize these attributes.

Jubbītes.—Mut’azilites who followed the philosophical teaching of Ja‘far ul-Mahāmert of Basra.

Kāmilites.—A main class of the Shi‘ites (q.v.).

Kāmilites.—Mut’azilites, followers of Abī Kāmil, who condemned the companions (Anṣār) because they did not do allegiance to ‘‘All, man, and thing because it is better to accept man and thing from a person or a place. They are Ja‘farites who believe in Sādiq as the mahdi.

1 All these names are alternatively spelt Mo- instead of Mu-.
MAHRATTAS.

Naszámítás.—Mu'tazilites, followers of Ibrahim ibn Sayyâr
un-Nazzâm, who was an extremist in his teaching of man's free-will and other philosophical doctrines.

Nu'mânis.—Ghâlîites agreeing in some points with Hishâmites, but not in the right in the form of a body, yet not a body.

Nu'nâsirîs.—Ghâlîites who agree with the Ishaqites except that they lay more stress on the incorporation of the deity.

Qaddarîs.—The upholders of free-will (see above).

Qudâsîs.—Those who regard the rank of the imâm as closed with the death of Muâsî.

Râshidîs.—A term used by some writers to denote the Shi'ites as a whole: by others given to a class of the Shi'ites who forsook Ziyadites, because of their abuse the Companions.

Rashidís.—Tha'labites, followers of Rashid ibn-Tâbi', sometimes called 'Ushîrites ("tithers") because they differed from others on the question of tithe producing the land watered by rivers and canals.

Rizâmîs.—Kaisânites of Khorasân at the time of Abû Muslim, to whom they ascribed the imâmâte and the Spirit of God. They also believed in metempsychosis.

Saba'îs.—Ghâlîites, who followed Abdallah ibn Sabâ' (see Sittites).

Sa'dîs.—(a) Zaidites, followers of al-Hasan ibn Șî'îb, who agreed with the teachings of the Butîtes (above); (b) Murjîites, followers of Șî'îb ibn Amir, who united with the doctrines of their own sect with the Shi'ites.

Sa'dîs.—Ajârîa having no real communication with the children of believers until they had grown up and possessed Islam.

Shâbânitès.—Tha'labites, followers of Shab'în ibn Salâma, who was killed in the war against the Muslims. They chose chiefly in Jorjân and Armenia and agreed in doctrine with the Jahmîtes.

Shâmîsîs.—Ja'arîites, followers of Yahyâ ibn Abû Shamît.

Shi'îs.—See separate article.

Shi'îtés.—Those who said that God creates the actions of men, and men appropriate them.

Si'îts are those who ascribe eternity to all the attributes of God, whether they denote essence or action, or are of the class called descriptive attributes.

Si'îts, the same as Ziyadites (below).

Sulaimânites (Sulelmânis).—Zaidites, followers of Suleîmân ibn Șarîr, who held that the appointment to the imâmâte was a matter of the imâm's own free will, and that the imâm of Abû Bekr and Omar were equally both 'Ali as having a real claim.

Tha'labites.—A party of the Khârîjîtes, followers of Thâ'lab ibn Amir, who agreed with the Ajârîa except that he was friendly with the exiled mustaschiqs and actually adored the imámâte.

Tha'llabîs.—Murjîites who said that faith consists in the knowledge and confession of God and His apostle, and what the intellect is not capable of doing. What the intellect can do (or leave) is not of faith.

Thumâûnîs.—Mu'tazilites, followers of Thumâma ibn Ashrâs in the days of Mânum, who taught that all non-Muslims would be condemned to eternal ruin.

Tâmânîs.—Murjîites who taught that faith depends on obedience rather to the principles than to the commands of Islam.

UBLâzîds.—Murjîites who believed that any thing but idolatry made a man forsook him; that if a man died professing the unity of God his sins would not hurt him.

Wâ'îsâtes.—Those who, opposed to the Murjîites, pronounced judgment in this life; they are not counted as a separate sect by Sittites.

Wâ'îsâtes.—A name given to those who followed Wâşîl ibn 'Âth, the founder of Mu'tazilism, who denied the attributes of God, asserted the power of man over his own actions, taught the existence of a middle place between heaven and hell, and despised the parties of Qadîrîes and Qadâmîtes.

Yâsîdîs.—Ishaqites, called Yâsîdîs, because they followed the religion of the Sabians in the Koran, and believed that God would send an apostle to the Persians.

AUTHORS.—For the philosophy and theology of Ash'ârâ see M. A. F. Mehren, Exposé de la réforme de l'Islamisme par About' l-Hasan Ali al-Ash'ârî (Leiden, 1878); W. Spitta, Zur Geschichte Abû-Hslan Abû-Hsârâ's (Leipzig, 1876); M. Schling, Zur Geschichte des Ash'ârâkentums (Leiden, 1891); D. B. Macdonald, The Development of Muslim Theology, Jurisprudence and Constitutional Theory (London, 1903). The last work contains translations of the creeds of Ash'ârî and Nasafî (Matâmârî). A further bibliography of works on the faith and outlook of Islam will be found in D. B. Macdonald's Muslim Theology.

1 These names are alternatively spelt No.-instead of Na.
The Maharrattas have always been a separate nation or people, and still regard themselves as such, though nowadays they are all under British or Mahommedan jurisdiction. That is, they belong either to British India or to the nizam's dominions. There are indeed still three large native states nominally Maharrattas: that of Sindhia near the borders of Hindustan in the north, that of Holkar in Malwa in the heart of the Indian continent, and that of the gaekwar in Gujarat on the western coast.

But in these states the prince, his relatives and some of his ministers or officials only are Maharrattas; the mass of the people belong to other sections of the Hindu race. These states then are not to be included in the Maharratta nation, though they have a share in Maharratta history.

In general terms the Maharrattas, in the wider sense, may be described under two main heads: first the Brahman, and secondly the low-caste men. The Maharratta Brahman possesses, in an intense degree, the qualities of that famous caste, physical, intellectual and moral. They have generally the lofty, the grave, the spare upright figure, and the calm aspect which might be expected in a race maintained in great purity yet upon a broad basis. At other times they have proved themselves the most able and ambitious of all the Indo-Aryans. They are notably divided into two sections: the Konkanast, coming from the Konkan or littoral tract on the west coast below the Western Ghats mountains; and the Deshast, coming from the upland tract, to which great extent the names of Deshast have been many distinguished Deshasts, yet the most remarkable of all have been Konkanastas. For instance, the peshwas, or heads of the Maharratta confederation which at one time dominated nearly all Hindustan between the Deccan and the Ganges. Of these persons are still known, and to this day there are sequestered villages, nesting near the western base of the Ghats, which are pointed to as being the ancestral homes of men who two centuries ago belonged to the highest order of society.

Apart from the Brahman, the Maharrattas may be generally designated as Sudras, the humblest of the four great castes into which the Hindu race is theoretically divided. But the upper classes have eliminated them from early times, and many of the people who belong to the race, and yet are not full-blooded, are almost as refined in manner and speech as the Scythian tribes, which at a very early time overran India. The ordinary Maharrattas, who form the backbone of the nation, have the qualities of the lower class, as well as some of the higher. Though not powerful physique, as compared with the northern races of the Punjab and Oudh, they have much activity and an unsurpassed endurance. Born and bred in or near the Western Ghats mountains and the numerous tributary ranges, they have all the qualities of all the Brahman. In most of the recent battles of the modern wars, military service less and, betaking themselves mainly to cultivation and to the carrying business connected with agriculture. As husbandmen they are not remarkable; but as graziers, as cartmen, they have won both respect and revenue by the self-same signalized themselves, save as armourers and cloth-workers.

In the Konkan there are some superior proprietors termed Konkanasts. With this and perhaps some other exceptions, there are not large Maharratta landed estates, and there is no real property in the contracts of the superior tenure-holders whose position relatively to that of the peasantry has caused much discussion in other parts of India. There are indeed many Maharratta chiefs still resident in the country, much as though they were the heads of large landed properties, and the power of the landed proprietors has come to be vested in the hands of joint tenants. Under them the cultivators are by British arrangements placed in the position of peasant proprietors. These village communities have always existed as the social unit in the Maharratta territories, though more or less in name than in the village communities of Hindustan and the Punjab. They are the smallest units into the village, as those of the headmen (patal), the village accountants, &c., are in working order throughout the Maharratta country.

The Maharratta people is mainly fortunate in suffering and misfortune. Though patient and mild in temper in general, they have a latent warmth of temper, and if oppressed beyond a certain limit they would fiercely turn upon their tormentors. As a rule they are patient, and law-abiding, but traditions of plunder have been handed down to the present day, and they retain the predatory instincts of their forefathers. The neighbourhood of dense forests, steep hill-sides, and fastnesses hard to approach offers extraordinary facilities to plunderers for screening themselves from a pursuit which they can never break out, gains head with rapidity, and is suppressed with difficulty. In times of peace it is kept under, but during war, or whenever the bands of civil order are loosened, it becomes a cause of anxiety and a source of danger. The men have frankness and strength of character; they work hard in the fields, and as a rule evince domestic virtue.

The peasantry preserve a grave and quiet demeanor, but they have their humble ideas of gaiety, and hold their gayest songs on occasions of births or marriages. They frequently beguile their toil with carols. They like the gossipping and bartering at the rural inns, and in the larger towns, which are sometimes held in strikingly picturesque, but not unprofitable, society. Their social position is an aversion to the "the holy Brahman," holding the life and the person of a Brahman sacred, even though he be a criminal of the deepest dye. They have of course regarded the cow as equally sacred. There are restrictions of a moral character, but very few branches of the social system of the Maharrattas are out of line with the Maharrattas. Bluff good-nature, a certain jocoseness, a humour pungent and ready, though somewhat coarse, a hot or even violent disposition, are characteristics of Maharratta chiefmen.

They usually show little aptitude for business or for sedentary pursuits, and on the other hand, they are born equestrians and sportsmen. Maharratta ladies and princesses have often taken a prominent part, for good or evil, in public affairs and dynastic intrigues. Apart from the Brahman, the Maharrattas have never done much for literature. Nor have they been distinguished in industrial art. Their architecture in wood, however, was excellent; and the teak forests of their country afforded the finest timber for building or for carving. They had also much skill in the construction of works for the supply of drinking water on a large scale and for irrigation.

The range of the Western Ghats enabled the Maharrattas to rise against their Mahommedan conquerors, to reassert their Hindu nationality against the whole power of the Mogul Empire, and to establish in its place an empire of their own. It is often stated that in India British conquest or annexation succeeded Mahommedan rule; and to a considerable extent this was the case. But, on the other hand, the principal power, the widest sovereignty, which the British overthrew in India was that of the Maharrattas.

During the earlier Moslem invasions in 1100 and in subsequent years, the Maharrattas do not seem to have made much resistance. They submitted to several Mahommedan kings under varying circumstances of those times. It was against the Mahommedan king of Bijapur in the Deccan that Sivaji, the hero of Maharratta history, first rebelled in 1657. Sivaji and his fighting officers were Maharrattas of humble caste, but his ministers were Brahman. When the Mogul Empire absorbed the Bijapur kingdom he defied the emperor. He impared a self-reliant enthusiasm to his countrymen, formed them into an army, and organized them as a political community; his mountaineer infantry, though limited in numbers, proved desperately courageous; his cavalry was daring and ubiquitous. The Moslems, having once overcome the Hindus in almost all parts of India, had not for centuries met with any noteworthy uprising. Sivaji, however, planned their expulsion, and before the end of his restless life made much progress in the execution of that design. The new state which he founded was maintained under various vicissitudes after his death. Maharratta resistance, once aroused by him, was never extinguished, and the imperial resources were worn out by ceaseless struggle, though vain efforts to quell it.

The great Mogul emperor's impoverished and embattled state was fain to recognize the Maharratta state by a formal instrument. The Maharratta king, a descendant of Sivaji, had become a raja fainant, and the arrangement was negotiated by his Brahman minister, whose official designation was the peshwa. The office of peshwa then became heireditary in the minister's family,
and grew in importance as the Mahratta kingdom rose, while the king sunk into the condition of a puppet. Thus the Mahratta power was consolidated throughout nearly the whole of Maharastra under the Brahman peshwa as virtual sovereign, with his capital at Poona, while the titular Mahratta raja or king had his court at the neighbouring city of Satara. Despite his political importance, however, the raja was still venerated as the descendant of Sivaji.

Then several chiefs carved out principalities of their own from among the ruins of the Mogul Empire. Thus Raghoji Bhonsla established himself in the tracts lying underneath the southern base of the Satpura range (namely, Nagpur and Berar), overran Orissa and entered Bengal. Damaji Gaekwar descended from the Western Ghats upon the alluvial plains of Gularat around Baroda; Tukoji Holkar subdue the uplands of Malwa beyond the Vindhya range on the north bank of the Nerbudda; and Mahadji Sindhiya obtained possession of large tracts immediately south of Agra and Delhi, marched into Hindustan and became virtually the master of the Mogul emperor himself (see Gwalior). Sivaji's own father had founded a dominion at Tanjore in the extreme south, which, however, never had relations with the central power at Poona. The same may be said of the state of Kolhapur, allotted to a younger branch of Sivaji's family.

But these principalities, though independent respecting internal administration, and making war or peace with their neighbours according to opportunity, owned allegiance to the peshwa at Poona as the head of the Mahratta race. On state occasions heads of principalities would visit Poona by way of acknowledging the superior position of the peshwa. On the other hand, the peshwa was careful to obtain the sanction of his nominal sovereign at Satara to every important act of state. Thus a confederation was formed of which the Brahman peshwa or head was at Poona, governing the adjacent territories, while the members, belonging to the lower castes, were scattered throughout the continent of India. Such was the Mahratta Empire, which supplanted the Mogul Empires in power, and that was the rising power to which the British were compelled to address themselves. It was, in fact, in order to meet the Mahrattas that the British undertook to organize the British Army in India. The forces of that great empire were, however, not yet formidable.

The first collision with the English occurred in 1775, arising from a disputed succession to the peshwaship. The English government at Bombay supported one of the claimants, and the affair became critical for the English as well as for the Mahrattas. It was at this juncture that Warren Hastings displayed his political genius and rendered signal service to his country, by succouring from Bengal the defeated Bombay army and negotiating a peace (in 1783) that restored the status quo.

The next collision happened in 1803. The peshwa had fallen into grave difficulties with some of the principal members of the Mahratta confederation, and therefore placed himself under British protection, and this led to the great Mahratta War, in which the Marquis Wellesley displayed those talents for military and political combination which rendered him illustrious. It was during the campaigns which ensued that General Arthur Wellesley defeated Sindhiya and the Bhonsla raja at Assaye, and General Lake won the victories of Farrukhabad, Dig and Laswari over Sindhiya and Holkar. The three confederates, Sindhiya, Holkar and the Bhonsla, concluded peace with the British government, after making large sacrifices of territory in favour of the victor, and submitting to British control politically. It was during these events that the British won the province of Orissa, the old Hindustan afterwards part of the North-Western Provinces, and a part of the western coast in Gujarat.

The third collision came to pass between 1816 and 1818, through the conduct, not only of the confederates, but also of the peshwa (Baji Bao) himself. During the previous war the peshwa had been driven to Thana, that is, to Bombay; since the war he had fallen more completely than before under British protection—British political officers and British troops being stationed at his capital. He apparently felt encouraged by circumstances to rebel. Holkar and the Bhonsla committed hostile acts. The predatory Pandaris offered a formidable resistance to the British troops. So the peshwa ventured to take part in the combination against the British power, which even yet the Mahrattas did not despair of overthrowing. After long-protracted machinations, he attacked the British at Kirked, but failed utterly, and fled a ruined man. Ultimately he surrendered to Sir John Malcolm, and was sent as a state pensioner to Bithur, near Cawnpore. The British, however, released the raja of Satara from the captivity in which he had been kept during the peshwa's time, and reinstated him on the throne, with a limited territory. Owing to these events the British government became possessed of the Konkan and of the greater part of the Deccan.

It remains to mention briefly the fortunes of each remaining member of the once imperial confederation. The principality of Satara was held to have lapsed in 1848 by the death of the
rāja without linear heirs, and was annexed by the British government. The Bhonsla rāja of Nagpur died without linear heirs in 1853, and his territory was likewise annexed. The house of Holkar remained faithful to its engagements with the British government, and its position as a feudatory of the empire was maintained. In Sindhia’s territory, by reason of internal feuds, the British had to undertake measures which were successfully terminated after the battles of Maharajpur and Panniar in 1843. But on the whole the house of Sindhia remained faithful. Sindhia himself was actively loyal during the Mutiny. The gaekwar gradually fell under British control towards the close of the 18th century, and his house never engaged in hostilities with the British government. The ex-pēshāva lived to old age at Bithur, and died in 1857. His adopted son grew up to be the Nana Sahib, of infamous memory, who took a leading part in the Mutiny.

See J. Grant Duff, History of the Mahrattas (3 vols., 1826); T. D. Broughton, Letters written in a Mahratta Camp (1813); M. G. Ranade, Rise of the Maratha Power (Bombay, 1900). (R. T.; J. S. Co.)

MAHSEER, or MAHSEER (Barbus mosal), a kind of barbel, abundant in the rivers of India, especially in pools in the upper and middle reaches of the Indus, Ganges, and Yamuna, and in mountainous part of the country. It is one of the largest species of the Cyprinid family, attaining to a length of 3 to 5 ft., and sometimes exceeding a weight of 70 lb. Its body is well-proportioned, rather elongate, and somewhat like that of the European barbel, but covered with very large scales, of which there are only twenty-five or twenty-seven placed along the lateral line; the dorsal fin is armed with a long and strong spine, and the mouth provided with four slender and short barbels. The lips are sometimes produced into fleshy lobes. To the fisherman in India the mahseer affords the same kind of sport as the salmon in the British Isles, and it rivals that fish as regards size, strength and activity. Its flesh is likewise much esteemed.

MAI, ANGELO (1782–1854), Italian cardinal and philologist, was born of humble parents at Schilpario in the province of Bergamo, Lombardy, on the 7th of March 1782. In 1799 he entered the Society of Jesus, and in 1804 he became a teacher of classics in the college of Naples. After completing his studies at the Collegium Romanum, he lived for some time at Orvieto, where he was engaged in teaching and palaeographical studies. The political events of 1808 necessitated his withdrawal from Rome (to which he had meanwhile returned) to Milan, where in 1813 he was made custodian of the Ambrosian library. He now threw himself with characteristic energy and zeal into the task of examining the numerous MSS. committed to his charge, and in the course of the next six years was able to restore to the world a considerable number of long-lost works. Having withdrawn from the Society of Jesus, he was invited to Rome in 1819 as chief keeper of the Vatican library. In 1833 he was transferred to the office of secretary of the congregation of the Propaganda; on the 12th of February 1838 he was raised to the dignity of cardinal. He died at Castelgandolfo, near Albano, on the 8th of September 1854.

It is on his skill as a reader of palimpsests that Mai’s fame chiefly rests, To the period of his residence at Milan belong: Fragments of Cicero’s Pro Scauro, Pro Tullio, Pro Flacco, In Clodium et Carthorum, De aevo alieno Milonis, De rege (Alexandrin 1814); M. Corn. Frontonii operis ineditae, cum epistolis item ineditis, Antoninis Ptil, Marti Aurelii, Lucii Veri et Appiani (1815; new ed., 1823, with more than 100 additional letters found in the Vatican library); portions of eight speeches of Quintus Aurelius Symmachi; fragments of Plautus; the oration of Isaeus De hereditate Cleonwym; the last nine books of the Antiquitates of Dionysius of Halicarnassus, and a number of other works. M. Tullii Ciceronis de republica qua supersedit appeared at Rome in 1822; Scriptorum veterum nova collectio, et vaticanis codicibus edita in 1825–1838; Clasici scripitores et vaticanis codicibus editi in 1828–1838; Speculum Romanum in 1839–1844; and Patrum nova bibliotheca in 1845–1853. His edition of the celebrated Codex Vaticanus, completed in 1838, but not published (ostensibly on the ground of inaccuracies) till four years after his death (1858), is the least satisfactory of his labours and was superseded by the edition of Vercellone and Cozza (1868), which itself leaves much to be desired. Although Mai was not as successful in textual criticism as in the decipherment of manuscripts, he will always be remembered as a laborious and persevering pioneer, by whose efforts many ancient writings have been rescued from oblivion.

See B. Prina, Biografia del cardinale Angelo Mai (Bergamo, 1822), a scientific work, which gives a full and, at the same time, a just appreciation of his work; Cozza-Luzi, Epistolario del card. Angelo Mai (Bergamo, 1883); life by G. Poletto (Siena, 1887).

MAIA, in Greek mythology, the eldest of the Pleiades, the seven daughters of Atlas and the Oceanid Pleione. She and her sisters, born on Mt Cyllene in Arcadia, are sometimes called mountain goddesses. In a cave of Cyllene Maia became by Zeus the mother of the god Hermes. The story is told in the Hymn to Hermes attributed to Homer. She was identified by the Romans with Maia Majesta, an old Italian goddess of spring, to whom a sacrifice was offered on the 1st of May by the priest of Vulcan.

MAIDA, a town of Calabria, Italy, in the province of Catanzaro, formerly known as Nana, is 18 m. W. S.W. direct, and 12 m. N.N.E. of Pizzo by rail (the station is 8 m. W. of the town). Pop. (1901), 5190. The town gives its name to the plain of Maida, where in 1866 British troops under Sir John Stuart defeated the French under Regnier. The names Maida Hill and Maida Vale in London are derived from this battle.

MAIDAN, an Indian term for any open plain. The Maidan is the name of the park in Calcutta, surrounding Fort William, where society people drive in the afternoon. The name is also applied to one of the valleys in the Afridi country of Tirah, and to the plateau portion of the state of Mysore.

MAIDEN, or MAID, a young unmarried girl. “Maid” is a shortened form of “maiden,” O. Eng. maegden, which represents a diminutive of a Teutonic word meaning “young person,” of either sex. An old English word “may,” meaning a kinsman or kinswoman, and also a virgin or girl, represents the original. In early usage “maiden” as meaning “virgin” is frequently applied to the male sex, thus, in Malory’s Morte d’Arthur, Sir Perceval is called “I am the only maiden of the round table.” Apart from the direct applications of the word to the unmarried state, such as “maiden name,” “maiden lady,” &c., the word is used adjectively, implying the preservation of the first state of an object, or indicating a first effort of any kind. Probably a “maiden” fortress is one which has never fallen, though the New English Dictionary suggests that the various “maiden castles” in England, usually ancient earthworks, may have been so called from being so strong that they could be defended by maidens, and points out that Edinburgh Castle, called “maiden-castle” by William Drummond of Hawthornden (Speech for Edinburghe to the King), is styled Castrum puerilum, “the castle of the maidens,” in Geoffrey of Monmouth. A “maiden” assize, circuit or session is one at which there are no prisoners for trial; a “maiden over” or “maiden” in cricket is an over from which no runs are scored. A “maiden speech” is the first speech made by a member of parliament in the house. In the Annual Register for 1794 (quoted in N. E. D.) the expression, with reference to Canning’s first speech, is said “to be according to the technical language of the house.” “Maiden” is applied to several objects, to a movable framework or horse for drying and airing of linen, to a washerwoman’s “dolly” or wooden beater, to the “kinnbaby” formed of the last sheaf of corn reaped which formerly figured in the Scottish harvest homes, and to the beheading instrument, known as the “Scottish maiden” (see below). “Maid,” apart from its primary sense of an unmarried woman, is chiefly used for a domestic female servant, usually with a qualifying word prefixed, such as “housemaid,” “parlourmaid,” &c.

The title of “MAID OF HONOUR” is given to an unmarried lady attached to the personal suite of a queen. The custom of sending young girls of noble or good birth to the court of a
ever, survives in Ockwells, a short distance south of the town. The stone bridge carrying the London road over the Thames dates from 1772; but the crossing is of ancient importance. Maidenhead has trade in malt and grain. The borough is under a mayor, 4 aldermen and 12 councillors.

The history of Maidenhead (Maydenhut, Maydenith) is bound up with that of the ancient bridge. It is not mentioned in Domesday. Edward I. (1297) gave a grant of pontage in aid of the bridge, which was almost broken down; similar grants to the “bailiffs and good men of Maydenith” were made by succeeding sovereigns. In 1451 Henry VI. incorporated the guild of the Brethren and Sisters of Maydenith to provide certain necessaries for the celebration of Mass and to keep the bridge in order; the guild, dissolved at the Reformation, was revived by Elizabeth, who, however, later (1581) substituted for it a corporation consisting of a warden, bridgemaster, burgesses and commonalty: the governing charter until the 19th century was that of James I. (1685) incorporating the town under the title of the mayor, bridgemaster and burgesses. In 1400 Thomas Holand, earl of Kent, held the bridge in the interests of the deposed Richard II., but was eventually forced to retire. In 1643 a meeting took place in the town between Charles I. and three of his children. In the 18th century a considerable trade was done in carrying malt, meal and timber in barges to London: at that time three fairs were held which have now practically disappeared. The Wednesday market is held under a charter of Elizabeth (1582).

MAID MARIAN, a personage incorporated in the English legend of Robin Hood. There is no evidence that she had originally any connexion with the Robin Hood cycle. She seems to have been an essential feature of the morris dance, and in the may-game was paired sometimes with Robin-Hood, but oftener with Friar Tuck. The well-known pastoral play of Adam de la Hale, Jeu de Robin et Marion, and the many French songs on the subject, account for the association of the names. In the ballads on Robin Hood her name is twice casually mentioned, but there is a late ballad, by a certain S. G. (F. J. Child, English and Scottish Ballads, i. 210), which tells how Maid Marian sought Robin in the forest disguised as a page, and fought with him for an hour before she recognized him by his voice. S. G. was perhaps acquainted with the two plays, written in 1598, of The Downfall and The Death of Robert Earl of Huntingdon, by Anthony Munday and Harry Chettle. In The Downfall Matilda Fitz Walter escapes from the persecution of King John by following her lover to Sherwood Forest, where they took the names of Robin Hood and Maid Marian, and lived together until she was legally united. Perhaps this tale has some connexion with the romance of the outlaw Fulk Fitz Warin. Matilda or Mauhah, widow of theobald Walter, escaped from John’s solicitations by marrying the outlawed Fulk and following him to the forest. There were in semi-historical legends three Matildas pursued by King John, of whom particulars are given by H. L. D. Ward in his Catalogue of Romances (i. 502). Their several histories were fused by the Elizabethan dramatists, and associated with the Maid Marian of the morris dance, who up to that time had probably only a vague connexion with Robin Hood.

MAIDSTONE, a market town and municipal and parliamentary borough, and the county town of Kent, England, 41 m. E.S.E. of London by the South Eastern & Chatham railway. Pop. (1901), 33,516; area, 4,908 acres. It lies principally on the eastern bank of the river Medway, the modern part spreading over the western slopes of a picturesque valley, which is intersected and adorned by orchards and hop gardens, this being the richest agricultural district of Kent. The hop grounds form the so-called middle growth of Kent, and the town has the principal grain market in the county. Archbishop Boniface in 1260 established a hospital here (Newark hospital) for poor pilgrims, the chapel of which, with modern additions, is now St Peter’s Church. The parish church of St Mary, which had existed from Norman times, was demolished in 1395 by Archbishop Courtenay, who erected on the site the present church of All

prince or feudal superior, for the purpose, primarily, of education, goes back to early feudal times, and is parallel with the sending of boys to act as pages and squires to the feudal castles. The regular establishment of maids of honour (filles d’honneur) appears first in the royal court of France. This has usually been attributed to Anne of Brittany, wife of Charles VIII.; she had a group of unmarried girls of high rank at her court as part of her household, in whom she took a lively and parental interest, educating them and bestowing a dowry upon them on their marriage. A slightly earlier instance, however, has been found. When the young Margaret of Austria came to France on her espousal to Charles VIII., broken by his marriage to Anne of Brittany, there were in her train several filles d’honneur, whose names appear in the Comptes d’argenterie de la reine Marguerite d’Autriche, from 1484–1485 and 1488–1490 (Archives de l’empire K.K. 80 and 81 quoted by A. Jal, Dictionnaire critique de biographie et d’histoire). It is from the days of Francis I. that the chronques scandaluse begin which circle round the name of honour of the French court. The maids of Catherine de Medici, celebrated as the “flying squadron,” l’escadron volant, are familiar from the pages of Pierre de l’Estoile (1574–1611) and Brantôme. Among those whose beauty Catherine used in her political intrigues, the most famous were Isabelle de Limeuil, Mlle de Montemory-Fosseux, known as la belle Fossense, and Charlotte de Baune. The filles d’honneur, as an institution, were suppressed in the reign of Louis XIV., at the instigation of Mme de Montespan—who had been one of them—and their place was taken by the dames de palais. In the English court, this custom of attaching “maids of honour” to the queen’s person was no doubt adopted from France. At the present day a queen regnant has eight maids of honour, a queen consort four. They take precedence next after the daughters of barons, and where they have a right or courtesy a title of their own, they are styled “Honourable.”

The SCOTTISH MAIDEN was an instrument of capital punishment formerly in use in Scotland. It is said to have been invented by the earl of Morton, who is also said to have been its first victim. This, however, could not have been the case, as the maiden was first used at the execution of the inferior agents in the assassination of Rizzio (1565) and Morton was not beheaded till 1561. The maiden was practically an early form of Guillotine. A loaded blade or axe moving in grooves was fixed in a frame about ten feet high. The axe was raised to the full height of the frame and then released, so that it would descend on a victim within reach. At last death by the maiden, including the regent Morton, Sir John Gordon of Haddo, President Spottiswood, the marquis and earl of Argyll. In 1710 it ceased to be used; it is now preserved in the museum of the Society of Antiquaries of Scotland, in Edinburgh.

MAIDHAIR, in botany, the common name for a fern, Adiantum Capillus-Veneris, characterized by the spreading hairs like needles at the end of the frond, the ultimate pinnules of which are nearly 1 in. long with a rounded crenate outer edge and repeatedly forked veins; the sori (or masses of spore-capsules) are in the pinnules of the pinnules, and are protected by a kidney-shaped involucre. The plant is widely distributed in temperate and tropical regions, and is occasionally found in the western counties of England, the Isle of Man, and west Ireland, growing on damp rocks or walls especially near the sea. The genus Adiantum is a large one containing many handsome species both tropical and temperate, well known in greenhouse and hothouse cultivation.

MAIDHAIR-TREE is a popular name for Gin sequencing lobata, a remarkable and handsome gymnospermous tree, the fan-shaped leaves of which with their forked veins recall those of the maidenhair (see GYMNOSPERMS).

MAIDHEAD, a market town and municipal borough in the Wokingham parliamentary division of Berkshire, England; 243 m. W. of London by the Great Western railway. Pop. (1901), 12,980. Area, 2,725 acres. It is pleasantly situated on and above the west (right) bank of the Thames, and is much in favour as a residential town and a resort of boating parties. Though of high antiquity it is wholly modern in appearance, and a large number of handsome houses have been built in its vicinity. A beautiful timbered house of the 15th century, how-

Saints. This fine Perpendicular building contains, besides many excellent monuments, the richly carved sedilia and the twenty-eight black seats used by the collegiate priests. Courtenay also founded a college of secular canons, the ruins of which are an interesting specimen of 14th-century architecture. From the reign of John until the Reformation the archbishops had a residence here, at which Stafford and Courtenay died. This Perpendicular building, with its Elizabethan east front, was acquired by the corporation as a memorial of Queen Victoria's Jubilee in 1887, and houses the school of science and art. The rector, with the manor, passed into lay hands at the Reformation; and, having been a perpetual curacy for three hundred and twenty years, the living became a vicarage in 1866. The grammar school was founded in 1549, and endowed with the estates of the local Corpus Christi fraternity, then dissolved; the hall in which the gild assembled remains, but the school is established in modern buildings on a new site. There are oil-mills, rope, sacking and twine factories, and cement, lime, and brick works. There is a considerable carrying trade on the Medway. A museum, with public library, was opened in 1858, in an interesting building of the early part of the 16th century. This is the headquarters of the Kent Archaeological Society, founded by the Rev. L. B. Larking in 1838. In 1890 an art gallery was added. The West Kent and General hospital, the county ophthalmic hospital, county gaol and barracks may be mentioned among other institutions. From Saxons times down to 1830 condemned malefactors were executed, and all the great county meetings were held, on Penenden Heath, a common situated about a mile north-east of the town, and enclosed by the corporation as a public recreation ground. The parliamentary borough of Maidstone returns one member. The town is governed by a mayor, 6 aldermen and 18 councillors.

There is evidence of a Roman settlement at Maidstone. The name Maidstone (Medwegeston, Meddestane, Maydestan), probably meaning Medway Town, is presumably of Saxon origin. At the time of the Domesday Survey it belonged to the archbishop of Canterbury, and from the reign of John the archbishops had a residence there. Its position in the centre of Kent gave it an early importance; the shire-moot was held at Maidstone in the 11th century, and Maidstone was an assize town in the reign of Edward I. In 1253 Crammer exchanged the manor of Maidstone with the king, and it was granted by Edward VI. to Sir Thomas Wyatt. Edward also incorporated the town by the title of the mayor, jurats and commonalty; it had formerly been governed by a portrewe and 12 "brethren." This charter was forfeited through Wyatt's rebellion; a second charter was granted by Elizabeth in 1559 and confirmed by subsequent sovereigns. A new charter constituting a governing body of a mayor, 12 jurats and 40 common counsels was given at the petition of the inhabitants by George II. in 1747, and remained the governing charter until 1835. Four fairs were granted by the charter of 1559; these are now held on the 13th of February, the 3rd of May, the 20th of June and the 17th of October. A Thursday market was granted by Henry III. to Archbishop Boniface, and a market every second Tuesday in the month by charter of George II. A corn market on Tuesday and a cattle market on Thursday are still held. The manufacture of linen and woollen goods was introduced by Wallowns, who settled here in 1597. This was succeeded by paper-making, now the chief industry of the town. The cultivation of hops has been carried on since the 17th century.

Maidstone has been associated with various incidents of general history. Wat Tyler broke into the prison, liberated John Ball the rebel preacher, and committed various depredations. Several of the leading inhabitants joined Jack Cade's rising. The rising of the Kentish Royalists in 1648 collapsed at Maidstone, where on the 1st of June Fairfax, after five hours' obstinate fighting, captured the town at midnight.

See Victoria County History, Kent; I. M. Russell, History of Maidstone (1881).

MAIHAR, a native state of Central India, in the Baghelkhand agency. Area, 407 sq. m.; pop. (1901), 63,702; estimated revenue, £4,700. The state, which is watered by the Tons river, consists mainly of alluvial soil covering sandstone, and is fertile except in the hilly district of the south. A large area is under forest, the produce of which provides a small export trade. The chief, whose title is raja, claims descent from the Kachwaha Rajput clan. The state suffered severely from famine in 1896–97. The town of Maihar (pop. 6,802) is on the East Indian railway, 97 m. N. of Jubbalpore. Extensive ruins of shrines and other buildings in its neighbourhood indicate a former much greater extent of the place.

MAIL. (1) (Through Fr. maille, from Lat. macula, a spot or hole, the mesh of a net), properly a metal ring or link which, joined closely with other links, formed the fabric of body and other armour in the middle ages, till it was superseded by plate-armour. The word "mail," properly applied to this form of chain-armour, is also used of armour generally, whether plate or chain, and is also transferred to the hornio defensive coverings of animals, such as the tortoise, crab, &c. (see ARM AND ARMOUR). (2) (O. Eng. maild, speech; probably the same as O. Saxo. malad, assembly; in meaning connected with O. Norn. mald, stipulation), a Scots law term meaning rent, tax. "Mails and duties" are the rents, whether in kind or money, of an estate. In English the word only survives in "blackmail" (q.v.). (3) (Through O. Fr. mâle, mod. mâle, a Teutonic word surviving in Dutch maaal), properly a bag, especially one used in travelling; this word, which appears in Chaucer, is now applied chiefly to the despatch and delivery of postal matter. In this sense "mail" is properly a bag in which such matter is conveyed, and hence is applied to the contents of the mail, postal matter collectively, and to the train, cars, or other means used in the despatch and delivery of the same. In general usage "mail" is confined to the "foreign" as opposed to the "inland" despatch of letters, &c., and to which the word "post" is chiefly applied; in official language, the word refers to the inland despatch. The word appears also in "mail-coach," a coach used for conveying the mail, and in "mail-cart," a cart similarly employed. This word is also applied to a light low vehicle propelled or drawn by hand, suitable for young children. The "mail phaeton" is a type of phaeton with high seat for two persons and drawn by a pair of horses.

MAILLY, LOUISE JULE, COMTESSE DE (1710-1751), mistress of Louis XV. of France, was the daughter of Louis, marquis de Néset. She was the eldest of three sisters who succeeded one another as favourites of the king. In 1726 she married her cousin, Louis Alexandre de Maillé. Although Louis XV. had paid her attentions from 1732, she did not become titular mistress until 1738. She did not use her position either to enrich herself or to interfere in politics. She was supplanted by her sister, the duchess of Châteauroux, and obliged to leave court in 1742.

See Enfant, J. de Gousson, La Duchesse de Châteauroux et ses sceurs (1894); Toussaint, Anecdotes curieuses de ..., Louis XV. (2 vols., 1905); J. B. H. R. Capefigue, Mesdamesseilles de Néset et la jeunesse de Louis XV. (1864).

MAIMANA, a town and khanate of Afghan Turkestan. The town is situated 200 m. S.W. of Balkh, and only some 25 m. from the frontier of Russian Turkestan. It is about two-thirds the size of Herat, square built and surrounded by a ruined wall and moat. The khanate was for long in dispute between Bokhara and Kabul, but in 1868 Abdur Rahman laid siege to the town, and it was compelled to come to terms. Its political status as an Afghan province was definitely fixed by the Russo-Afghan boundary commission of 1885. The inhabitants are chiefly Uzbegs.

MAIMAND, a town in the province of Fars, Persia, a few miles east of Firuzabad and about 70 m. from Shiraz. It has a population of about 3000, almost wholly occupied with the manufacture and sale of rose-water, which is largely exported to many parts of Persia as well as to Arabia, India and Java. The district also produces great quantities of almonds. The
rose gardens cover several square miles. In 1349 a great part of
Maimond and of three little villages belonging to it became
wack (pious endowment) of the shrine at Shiraz of Mir Ahmed,
surnamed Shah Chirag, a son of Musa Kazim, the seventh imam
of the Shiias, and the remainder of the Maimond grounds
was given to the shrine by Mir Habbib Ulah Shareri and by
Shah Ismail in 1504; the administration of the Maimond
property as well as the guardianship of the shrine is still with
the descendants of Mir Habbib Ulah.

MAIMBOURG—MAIMONIDES

MAIMBOURG, LOUIS (1610-1686), French Jesuit and
historian, was born at Nancy. He entered the Society of
Jesus at the age of sixteen, and after studying at Rome became
a classical master in the Jesuit college at Rouen. He afterwards
devoted himself to preaching, but with only moderate success.
After having taken some part in minor controversies he threw
himself with energy into the dispute which had arisen as to
the Gallican liberties; for his Trast historique sur les prérogatives
de l'Église de Rome (1682) he was by command of Louis XI.
expelled from the Society, but rewarded by Louis XIV. with
a residence at the abbey of St Victor, Paris, and a pension.
He died on the 13th of August 1686. His numerous works include
histories of Arianism, the iconoclastic controversy, the Greek
schism, Lutheranism, Calvinism, and of the pontificates of
Leo I. and Gregory I; they are mere compilations, written
indeed in a very lively and attractive style, but inaccurate
and untrustworthy.

The History of Arianism was published in English (1728-1729) by
William Webster, with an appendix on the English writers in the
Socinian and Arian controversies.

MAIMING, mutilation, a physical injury which involves
the loss of, or incapacity to use, a bodily member. The verb
"to maim," in M. E. mayne, makayme, mayme, &c, was adopted from O. Fr. "mêner;" cf. It. magazzurre, Med. Lat. mahemiens
makennare, &c. (see Du Cange, Gloss., s.v. "Mahanium").
Maiming or mutilation is and has been practised by many
races with various ethical and religious significances, and
was a customary form of punishment on the principle of an
"eye for an eye" (see MUTILATION). In law "maiming"
is a criminal offence; the old law term for a special case of
maiming of persons was "mayhem" (q.v.), an Anglo-French
variant form of the word. Maiming of animals by others than
their owners is a particular form of the offences generally
grouped as "malicious damage." For the purpose of the
law as to this offence animals are divided into cattle, which
includes horses, pigs and asses, and other animals which are
either subjects of larceny at common law or are usually kept
in herds or flocks for domestic purposes. The punishment
for maiming of cattle is three to fourteen years' penal servitude.
Malicious injury to other animals is a misdemeanour punishable
on summary conviction. For a second offence the penalty is
imprisonment with hard labour for over twelve months.
(Malicious Damage Act 1861.) Maiming of animals by their
owner falls under the Cruelty to Animals Acts.

MAIMON, SALOMON (1754-1800), German philosopher,
was born of Jewish parentage in Polish Lithuania, and died
at Nieder-Siegensdorf on the 22nd of November 1800. He
married at the age of twelve, and studied medicine in Berlin.
In 1770 he severed his connexion with his orthodox co-religionists
by his critical commentary on the Moreh Neuhim of Maimonides,
and devoted himself to the study of philosophy on the lines of
Wolf and Moser Mendelssohn. After many vicissitudes he
found a peaceful residence in the monastery of Count Kalkreuth
at Nieder-Siegensdorf in 1790. During the ensuing ten years
he published the works which have made his reputation as a
critical philosopher. Hitherto his life had been a long struggle
against difficulties of all kinds. From his autobiography,
it is clear that his keen critical faculty was developed in great
measure by the slender means of culture at his disposal. It
was not till 1788 that he made the acquaintance of the Kantian
philosophy, which was to form the basis of his life-work, and
as early as 1790 he published the Versuch über die Transcendent-
philosophie, in which he formulates his objections to the system.
He seizes upon the fundamental incompatibility of a conscious-
ness which can apprehend, and yet is separated from the "thing-in-itself." That which is object of thought cannot be
outside consciousness; just as in mathematics \( \sqrt{-1} \) is an un-
real quantity, so "things-in-themselves" are ex hypothesi outside
consciousness, i.e. are unthinkable. The Kantian paradox he
explains as the result of an attempt to explain the origin of the
"given" in consciousness. The form of things is admittedly
subjective; the mind endeavours to explain the material of the
given in the same terms, an attempt which is not only impossible
but involves a denial of the elemental laws of thought. Know-
ledge of the given is, therefore, essentially incomplete. Complete
or perfect knowledge is confined to the domain of pure thought,
to logic and mathematics. Thus the problem of the "thing-in-
itself" is dismissed from the inquiry, and philosophy is limited
to the sphere of pure thought. The Kantian categories are,indeed, demonstrable and true, but their application to the
given is meaningless and untractable. By this critical scepticism
Maimon takes up a position intermediate between Kant and
Hume. Hume's attitude to the empirical is entirely supported
by Maimon. The general concept, as given by experience,
expresses not a necessary objective order of things, but an
ordered scheme of conception; it is subjective and cannot be
postulated as a concrete law apart from consciousness. The
main argument of the Transcendentalphilosophie not only drew
from Kant, who saw it in MS., the remark that Maimon alone
of his all critics had mastered the true meaning of his philosophy,
but also directed the path of most subsequent criticism.

Maimon's chief works, in addition to the above quoted, are
Philos. Wörterbuch (1791); Streden im Gebiete der Philos. (1793);
Über die Progresse der Philos. (1797); Die Kategorien des Aristoteles
mit Anmerkungen erläutert (1794); Versuch einer neuen Logik (1794
and 1798); Kritische Untersuchungen über den menschl. Geist (1797).

beschrieben (1797), ed. K. P. Moritz; Eng. trans. by J. C. Murray,
(1888); Wolff, Maimoniana (1813); Witte, S. Maimon (1876).

MAIMONIDES, the common name of RASHI MOSES BEN
MAIMON (1135-1204), also known from the initials of these last
words as RAMBAM, Jewish philosopher. His life falls into	hree epochs, which may be typified by the towns in which
they were passed, viz. Cordova, Fez and Cairo. He was born in
Cordova on the 20th of March 1135, the eve of Passover;
he had a brother, David, and one sister. His early years were
spent in his native town, which had then just passed the zenith
of its glory. The Arab rulers had fostered the development
of science, art, medicine, philosophy, literature and learning.
All Jews had a free place in these palaces of Maimonides,
whose father, besides training him in all branches of Hebrew
and Jewish scholarship, implanted in the youth a sound
knowledge of these secular studies as well. In 1148 Cordova
was taken from the last Fatimite caliph by the victorious
Almohades, who had spread over Spain from N. Africa. These
militant revivalists strove to re-establish Islam in what they
considered its primitive simplicity. They laid great stress on
the unity of God, and tolerated neither schism within the faith
nor dissent without. The position of the orthodox Spanish
Jews became intolerable, and Maimon, after ten years of hard-
ships, wanderings and escapes, decided to take his family out
of the country. He settled in Fez. The years which Maimonides
spent there (1160-1165) were memorable for his friendship
with Abdul Arab Ibn Muḥājir - Moslem poet and theologian-
and for the commencement of his literary activity. His energies
were diverted towards stimulating the religious feelings of his
brethren and combating assimilation. In consequence he became
alarmed for his own safety, and in 1165 left for Egypt, where
he settled after a passing visit to the Holy Land. Cordova
taught him the humanities; Fez humanity. Cairo, besides giving
him prominence at court and in the Jewish community, was
the centre of the almost world-wide influence which he exercised
over Jewry by his monumental writings and dominant person-
ality. By 1177 Maimonides was the recognized chief of the
Cairene congregation and consulted on important matters by
communities far and wide. Here he was joined by his most
famous disciple, Joseph Aknin. But his early life in Egypt was fraught with deep sorrow. His father died soon after their arrival, and Maimonides himself suffered severely from prostration and sickness. His brother David, jointly with whom he carried on a trade in gems, was shipwrecked in the Indian Ocean. With him perished the entire fortune of the family. Forced to earn a livelihood, Maimonides turned to medicine. The fame of his skill eventually brought him the appointment of body physician to Saladin, to whom, it is said, he was so attached that when Richard I. wrote from Ascalon, offering him a similar post at the English court, Maimonides refused. He married the sister of Ibn al Mâli, one of the royal secretaries. In 1186, his son Abraham was born. His remaining years were spent in ceaseless activity and in controversy, which he sought to avoid. He died amidst universal sorrow and veneration.

The works of Maimonides fall into three periods: (a) To the Spanish period belong his commentary on the whole Talmud (not fully carried out), a treatise on the calendar (Mamarr ha-Haftorot), a treatise on logic (Mililoth Higgayon), and his commentary on the Mishnah (this was called Siraj or Maor, i.e., “Light”); begun 1158, completed 1168 in Egypt). (b) While he was in Fez, he wrote an essay on the sanctification of the name of God (Mizmar Kiddush Hashem, Igereth Hashemed). (c) The works written in Egypt were: Letter to the Yemenites (Iggereth Teman or Pelkah Tsippah); Responsa on questions of law; Biblical and Rabbinical Code (Mishneh Torah or Yad); and a complete 302-year calendar and an abridged handbook of the preceding; and his great philosophical work Moreh Nebukim or “the guide of the perplexed” (1190). To these must be added certain portions of the Mishnah commentary, such as the “high Chapters,” the discussion on reward and punishment and immortality, the Jewish Creed, which have acquired fame as independent works.

The influence of Moses ben Maimon is incalculable. “From Moses unto Moses there arose not one like Moses,” is the verdict of posterity. Maimonides was the great exponent of reason in faith and toleration in theology. One of the main services to European thought of the “Guide” was its independent criticism of some of Aristotle’s principles. His codification of the Talmud was equally appreciated in the study of the scholar and in practical life. Christian Europe owed much to Maimonides. Not only did his “Guide” influence scholasticism in general, but it was from his Code that the Church derived its medieval knowledge of the Synagogue.

A new English translation will be published in Maimonides, by David Yellin and Israel Abrahams (London, 1903); the final chapter of that work gives a summary of the influence of Maimonides on Christian philosophers such as Aquinas, and Jewish such as Spinoza. The “Guide” was translated into English by A. Friedland (1881–1885; new ed. 1905). See also Jewish Encyclopedia articles s.v., and the volumes edited by Guttmann, Moses ben Maimon (Leipzig, 1908, &c.).

MAIN—MAINA

MAINE (Lat. Moena), a river of Germany, and the most important right-bank tributary of the Rhine. It has two sources, the Weisse Main (White Main), which rises in the Fichtelgebirge on the east side of the Ochsenkopf, and the Rote Main (Red Main), which, rising on the eastern slope of the Frankish Jura, flows past Bayreuth. They unite 3 m. below Kulmbach, 920 ft. above the sea. Hence the river, already of considerable size, pursues a north-westerly direction, skirting the plains of the Frankish Jura in a pleasant valley. At Laichingen the river takes a south-westerly course, which it retains until entering the fertile basin of Bamberg. Here it receives from the south-east the waters of its chief tributary, the Regnitz, and enters upon its middle course. Its direction is now again north-west, and meandering through pleasant vales and pastures it passes Hassfurt and reaches Schweinfurt. Its course is now almost due south to Ochsenfurt, where it again proceeds north-west. Continuing in this direction amid vine-clad hills, it washes the walls of the university city of Würzburg, and thence, dividing the forest-clad ranges of the Spessart and the Odenwald, reaches Gärndien. Here it is joined from the right by the Frankish Saale and, turning abruptly south, reaches Wertheim the beautiful Tauber. Feudal castles and medieval towns now crown its banks, notably, Freudenberg and Miltenberg. From the latter it proceeds due north to Aschaffenburg, whence passing Frankfort it pours its yellow waters into the green waters of the Rhine just above Mainz. The Main has a total length of 310 m. and drains a basin of approximately 11,000 sq. m. It is navigable from the confluence of the Regnitz, 240 m. from its mouth, for barges and other small craft, and through the Ludwigs Canal is connected with the Danube.

See Ulrici, Das Maingebiet in seiner natürlichen Beschaffenheit (Kassel, 1885); E. Faber, Zur Hydrographie des Maingebietes (Munich, 1895), and Lill, MAINHAL, Main und Mainschifffahrt (Berlin, 1904).

MAIN (from the Aryan root which appears in “may” and “might,” and Lat. magnus, great), a word meaning properly power or strength, especially physical. This use chiefly survives in the expression “with might and main.” The word is more common as a substantival elliptical use of the adjective, which usually has the sense of principal or chief in size, strength, importance, &c. Thus “the main,” the high open sea, is for “main sea,” cf. “mainland,” the principal part of a territory excluding islands and sometimes far-projecting peninsulas. The expression “the Spanish main properly meant the haunt of the main line of the N. Coast of South America, stretching from the Orinoco to the Isthmus of Panama, and the former Spanish possessions in Central America bordering on the Caribbean Sea, but it is often loosely used, especially in connexion with the buccaneers, of the Caribbean Sea itself. The term “main” is also thus used of a principal pipe or cable for conducting gas, water, electricity, &c. The elliptical use does not appear, however, in such expressions as main road, line, stream. Another use of the word “main” has a somewhat obscure history. It appears as a term in the game of hazard, and also in cock-fighting. In the last it is used for a match, and for the cocks engaged in a match. In hazard it is the number called by the “caster” before the dice are thrown; this may be any number from five to nine inclusive. The usual derivation is from the French main, a hand, but according to the New English Dictionary there is no evidence for this, and the more probable explanation is that it is an adaptation of “main” meaning principal or chief. From this use of the word in hazard the expression “main chance” is derived. “Main,” a shortened form of domain or demesne, only now survives in Scotland, usually in the plural “mains” for a home farm.

MAIN (or MANI) and MAINOTES, a district and people of the Peloponnese, the modern Morea. Maina is the country occupied by the mountain range of Taygetus from Sparta to Cape Matapan, the ancient Taenarum. It is now divided between the modern districts Oetylos and Gythion. Before the organization of the present kingdom of Greece, Maina was subdivided into Ego Main, Outside Maina, from the frontier of Kalamata, on the Gulf of Messenia, to Vitylo (Oetylos) and inland to the summit of Taygetus; Kato Main, Lower Maina, from Vitylo to Cape Matapan; and Neo Main, or Inner Maina, on the east, and on the Gulf of Laconia as far as the plain of Elo. It contained over a hundred villages. The country is mountainous and inaccessible, a formation to which it owes its historical importance. The Mainotes claim to descend from the Spartans, and probably represent the Eleutheroi, or free Spartans who were delivered by Rome from the power of Sparta, as is suggested by the traces of ancient Greek in their dialect and by their physical type. Their country being a natural fortress, they were able to defend themselves against the Byzantine emperors, the barbarians who broke into the empire, the Latin princes of Achaia of the house of Villehardouin, and the Turks. As their country is also poor and maritime, they were early tempted to take to piratical adventure. Gibbon says that “in the time of Constantine Porphyrogenitus they had acquired the name of Mainotes, under which they disclaim the claim of liberty by the inhuman pillage of all that is shipwrecked on their rocky shore.” Their neighbours gave their country the name of “Kakaboulla”—the land of wicked counsels. The passes of their mountains were elaborately fortified and their villages were full of fortified towers.
Much Roman law in 1847, but in 1856 he contributed to the Cambridge Essays the essay on Roman law and legal education, republished in the later editions of Village Communities, which was the first characteristic evidence of his genius. Meanwhile he had become one of the readers appointed by the Inns of Court, in the first of their many half-hearted attempts at legal education, in 1832. Lectures delivered by Maine in this capacity were the groundwork of Ancient Law (1861), the book by which his reputation was made at one stroke. Its object, as modestly stated in the preface, was "to indicate some of the earliest ideas of mankind, as they are reflected in ancient law, and to point out the relation of those ideas to modern thought." Within a year of its publication the post of legal member of council in India was offered to Maine, then a junior member of the bar with little practice, few advantages of connexion, and no political or official claims. He declined once, on grounds of health; the very next year the office was again vacant. This time Maine was persuaded to accept, not that his health had improved, but that he thought India might not make it worse. It turned out that India suited him much better than Cambridge or London. His work, like most of the work done by Englishmen in India in time of peace, was not of a showy kind—its value is shown by the fact that he was asked to prolong his services beyond the regular term of five years, and returned to England only in 1869. The subjects on which it was his duty to advise the government of India were as much political as legal. They ranged from such problems as the land settlement of the Punjab, or the introduction of civil marriage to provide for the needs of unorthodox Hindus, to the question how far the study of Persian should be required or encouraged among European civil servants. On the civil marriage question in particular, and some years earlier on the still more troublesome one of allowing the remarriage of native converts to Christianity, his guidance, being not only learned but broad-minded, was of the greatest value. Plans of codification, moreover, were prepared, and largely shaped, under Maine's direction, which were carried into effect by his successors, Sir J. Fitzjames Stephen and Dr Whitley Stokes. The results are open to criticism in details, but form on the whole a remarkable achievement in the conversion of unwritten and highly technical law into a body of written law sufficiently clear to be administered by officers to many of whose ideas and language are foreign. All this was in addition to the routine of legislative and consulting work and the establishment of the legislative department of the government of India on substantially its present footing.

Maine's power of swiftly assimilating new ideas and appreciating modes of thought and conduct remote from modern Western life came into contact with the facts of Indian society at exactly the right time, and his abilities and other competent observers expressed the highest opinion of his work. In return Maine brought back from his Indian office a store of knowledge which enriched all his later writings, though he took India by name for his theme only once. This essay on India was his contribution to the composite work entitled The Reign of Queen Victoria (ed. T. H. Ward, 1887). Not having been separately published, it is perhaps the least known of Maine's writings; but its combination of just perception and large grasp with command of detail is not easily matched outside W. Stubbs's prefaces to some of the chronicles in the Rolls series, and (more lately) F. W. Maitland's monographs. As vice-chancellor of the university of Calcutta, Maine commented, with his usual pregnant ingenuity, on the results produced by the contact of Eastern and Western thought. Three of these addresses were published, wholly or in part, in the posthumous collection Village Communities; the substance of others is understood to be embodied in the Cambridge Rede lecture of 1875, which is to be found in the same volume. The practical side of Maine's experience was not long lost to India; he became a member of the secretary of state's council in 1871, and remained so for the rest of his life. In the same year
he was gazetted a K.C.S.I. In 1869 Maine was appointed to the chair of historical and comparative jurisprudence newly founded in the university of Oxford by Corpus Christi College. Residence at Oxford was not required, and the election amounted to an invitation to the new professor to resume and continue in his own way the work he had begun in *Ancient Law*. During the succeeding years he published the principal matters of his lectures in a carefully revised literary form: *Village Communities in the East and the West* (1871); *Early History of Institutions* (1875); *Early Law and Custom* (1883). In all these works the phenomena of societies in an archaic stage, whether still capable of observation or surviving in a fragmentary manner among more modern surroundings or preserved in contemporary records, are brought into line, often with singular felicity, to establish and illustrate the normal process of development in legal and political ideas.

In 1877 the mastership of Trinity Hall, Cambridge, where Maine had formerly been tutor, became vacant. There were two strong candidates whose claims were so nearly equal that it was difficult to elect either; the difficulty was solved by a unanimous invitation to Maine to accept the post. His acceptance entailed the resignation of the Oxford chair, though not continuous residence at Cambridge. Ten years later considerations of a somewhat similar kind led to his election to succeed Sir William Harcourt as Whewell professor of international law at Cambridge. His all too short performance in this office is represented by a posthumous volume which had not received his own final revision, *International Law* (1888).

Meanwhile Maine had published in 1885 his one work of speculative politics, a volume of essays on *Popular Government*, designed to show that democracy is not in itself more stable than any other form of government, and that there is no necessary connexion between democracy and progress. The book was deliberately unpopular in tone; it excited much controversial comment and some serious and useful discussion.

In 1886 there appeared in the *Quarterly Review* (clxxii. 180) an article on the posthumous work of J. F. McLennan, edited and completed by his brother, entitled "The Patriarchal Theory." The article, though necessarily unsigned (in accordance with the rule of the *Quarterly* as it then stood), was Maine's reply to the McLennan brothers' attack on the historical reconstruction of the Indo-European family system put forward in *Ancient Law* and supplemented in *Early Law and Custom*. Maine was generally adverse from controversy, but showed on this occasion that it was not for want of controversial power. He carried the war back into the invader's country, and charged J. F. McLennan's theory of primitive society with owing its plausible appearance of universal validity to general neglect of the Indo-European evidence and misapprehension of such portions of it as McLennan did attempt to handle.

Maine's health, which had never been strong, gave way towards the end of 1887. He went to the Riviera under medical advice, and died at Cannes on the 3rd of February 1888. He left a wife and two sons, of whom the elder died soon afterwards.

An excellent summary of Maine's principal writings may be seen in Sir Mountstuart Grant Duff's memoir. The prompt and full recognition of Maine's genius by continental publicists must not pass unmentioned even in the briefest notice. France, Germany, Italy, Russia have all contributed to do him honour; this is the more remarkable as one or two English publicists of an older school signally failed to appreciate him. Maine warned his compatriots against the insularity which results from ignorance of all law and institutions save one's own; his example has shown the benefit of the contrary habit. His prominent use of Roman law and the wide range of his observation have made his works as intelligible abroad as at home, and thereby much valuable information—for example, concerning the nature of British supremacy in India, and the position of native institutions there—has been made the property of the world of letters instead of the peculiar and obscure possession of a limited class of British public servants. Foreign readers of Maine have perhaps understood even better than English ones that he is not the propounder of a system but the pioneer of a method, and that detailed criticism, profitable as it may be and necessary as in time it must be, will not leave the method itself less valid or diminish the worth of the master's lessons in its use. The rather small bulk of Maine's published and avowed work may be explained partly by a fine literary sense which would let nothing go out under his name unfinished, partly by the drawbacks incident to precarious health. Maine's temperament was averse from the labour of minute criticism, and his avoidance of it was no less a matter of prudence. But it has to be remembered that Maine also wrote much which was never publicly acknowledged. Before he went to India he was one of the original contributors to the *Saturday Review*, founded in 1855, and the inventor of its name. Like his intimate friend Fitzjames Stephen, he was an accomplished journalist, enjoyed occasional article-writing as a diversion from official duties, and never quite abandoned it. The practice of such writing probably counted for something in the freedom and clearness of Maine's style and the effectiveness of his dialectic. His books are a model of scientific exposition which never ceases to be literature.

**MAINE**, an old French province, bounded N. by Normandy, E. by Orléanais, S. by Touraine and Anjou, and W. by Brittany. Before the Roman Conquest the region occupied by this province was inhabited by the Auleri Cenomanni and the Auleri Diablintes; under the Roman empire it consisted of two *civitates* comprised in the Province Lugudunensia Tertia—the Civitas Cenomannorum and the Civitas Diablintum, whose chief towns were Le Mans and Jublains. These two *civitates* were united during the barbarian period and formed a single bishopric, that of Le Mans, suffragan to the metropolitan see of Tours. Under the Merovingians and Carolingians the diocese of Le Mans corresponded to the Pagus Cenomanensis, and in the feudal period to the county of Maine. In the 16th century the county of Maine, with the addition of Perche, formed a military government—the province of Maine. Since 1790 this province has been represented approximately by the departments of Sarthe and Mayenne, the respective capitals of which are Le Mans and Laval. In 1853 the bishopric of Laval was separated from that of Le Mans. Maine was evangelized in the 3rd century by St Julian. After forming part of the kingdom of Syagrius, it was conquered by Clovis at the end of the 5th century. Owing to the scarcity of documents the history of Maine until the end of the 9th century is merged in the history of the bishops of Le Mans, which has come down to us in the *Actus pontificum Cenomanis in urbe de gentium le Mans, 1901*, composed under the direction of Bishop Aldric (832–857). Roger (c. 805–828) was perhaps the first hereditary count of Maine; the counts whose existence is certain are Hugh I. (c. 939–902), Hugh II. (before 902–1015), Herbert I. (1015–1032 to 1046), Hugh III. (1032–1036 to 1051), Herbert II. (1051–1062), William the Bastard (1063–1087), Robert Curthose (1087–1091), Hugh IV. (1091–1092) and Helias (1092–1110). Maine, which was in the vassalage of Anjou as early as the 9th century, was united to Anjou in 1110 by the marriage of Count Helias's daughter to Fulk V., count of Anjou, and passed to the English crown in 1154, when Henry Plantagenet (who was born at Le Mans) became king of England. In 1204, after the confiscation of the estates of John of England, Maine was united to France; in 1246 it was separated from France by Louis IX., who handed it over to his brother Charles, count of Provence. Again united to France in 1328, it was given in 1350 as an appanage to Louis, second son of John II., and did not
definitely return to the French crown until 1481, after the death of Charles II, count of Maine. During the Hundred Years' War Maine was taken in 1425 by the English, who lost it in 1448.

See Histoire de l'église du Mans, by Don Piolin (Paris, 1851-1858), which is useful but out of date; Revue historique et archéologique du Maine (1876); La Province du Maine (1893); B. Haurtin, Histoire littéraire du Maine (1870-1877).

MAINE, a North Atlantic state of the United States of America, the most north-easterly state in the Union, and the largest of the New England group. It lies between lat. 40° 27′ 21″ N., and between lat. 47° 27′ 33″ N., and between 66° 56′ 38″ and 72° 6′ 41″ W. It is bounded N.W. by the Canadian province of Quebec; N. and E. by the Canadian province of New Brunswick, from which it is separated in part by the natural barriers of the Saint John River, the Grand (or Schoodic) Lakes, the Saint Croix River, and Passamaquoddy Bay; S.S.E. by the Atlantic Ocean; and W. by New Hampshire, the Piscataqua and Salmon Falls rivers being the natural boundary lines at the S.W. The area of the state is 33,040 sq. m., 3,145 sq. m. being water surface.

Maine attracts more summer visitors than any other state in the Union. This is due to the cool and refreshing summer climate; the picturesque coast and its many islands, which are favourite grounds for camps and summer cottages; the mountains, and the beautiful lakes and rivers, many of them offering opportunities for good fishing and boating. Among the more widely known resorts are Mount Desert Island, on which is Bar Harbor, a fashionable summer place of great beauty; Long Island, Orr's and other islands in Casco Bay; Old Orchard, with a gently sloping white sand beach 9 m. long, Rangeley and Moosehead Lakes, favourite resorts of fishermen and hunters; Mt Katahdin, in the heart of the moose country; and Poland Springs (38 m. by rail from Portland) in Androscoggin county, near lake Aisagunticook.' 

About 1870, camps, summer cottages, summer hotels and boarding houses began to multiply throughout the state. The needs of this summer population gave a new impulse and a new turn to agriculture; and the demand for souvenirs revived among the Indians basket-weaving, moccasin-making, and such crafts.

Physical Features.—The surface is a gently rolling upland, forming the upper part of the "New England uplands," above which rise isolated mountain peaks and clusters of peaks, and below which are cut numerous river valleys. The highest peak is Mt Katahdin (5200 ft.), a little N.E. of the centre of the state in Piscataquis county, which is the highest point in the state. Mt Katahdin, in Franklin county, are most of the other high peaks of the state: Saddleback Mountain (4000 ft.), Mt Abraham (3388 ft.), Ragged Mountain (3060 ft.), and Lawless (3200 ft.). The upper and middle courses of many of the streams of this line of mountain peaks is the water-parting which divides the state into a north slope and a south slope. The north slope descends gently both to the N. and to the E.; although quite hilly in the lowest portion it is a large upland, covered with a cover of swamps and forests. The south slope contains nearly all the mountains and is generally more hilly, has a mean descent toward the sea of about 7 ft. to the mile, the fall being greatest in the W., where the mountains are high at the N. and the shore low at the S., and less to the E., where the water-parting is lower and the shore high and rocky.

After the uplift which caused the rivers to cut below the general "upland surface" and develop well-marked valleys for themselves, came the period of the great continental glaciation. The glacier or ice sheet overran all Maine, irregularly scouring out the bed rock to produce rock basins, damming up many river valleys with glacial deposits and completely disarranging the drainage lines. When the ice melted, the rock basins and the dammed-up valleys filled with water to produce lakes. This is the origin of the numerous lakes of Maine, which give it some of its most beautiful scenery, and help to make it one of the best second home places in the United States. The lakes are very numerous, scattered in nearly all parts of the state, and are especially numerous at high elevations, and have an aggregate area of more than 2000 sq. m. Few other regions have so many large lakes so variously situated, and with such beauty of aspect and surroundings. They contribute largely to a constant supply of water power for which the course of the rivers of S.W. Maine are exceptionally well adapted; many of them abound in trout, salmon, toge, black bass and pickerel, and near the coast are many marine fisheries. Lake (about 120 sq. m.; 35 m. long and from 2 m. to 10 m. wide), on the boundary between Piscataqua and Somerset counties, is the largest in Maine and the largest inland body of water wholly in the state; its surface is at the level of the ocean; and Mt Kineo rises abruptly to about 1750 ft. above the sea (about 700 ft. above the lake) on its eastern shore. Other lakes, such as the Rangeley Lakes, Chesuncook and Twin Lakes on the Penobscot, and St. Francis, have their outlets into the St. Croix River, the head waters of the Saint Croix River, equal or surpass Moosehead in picturesque- ness. The glacier or ice sheet, above referred to, de- posited and disarranged such an infinite variety of rock formations as to produce a succession of gorges and prominent ridges of the ice sheet to form the "hard-pan" referred to later. The glaciation is also responsible for the poor soil of most of the state, for, although the rocks are the same crystallines which give good soil to this further south in unglaciated regions, all the decayed portions of such rocks have been washed away, leaving fresh, barren rock over great areas, or depositing the rather sterile hard-pan as a thin coating in other places.

After the uplift came a period of subidence, during which this region sank one or more thousand feet, allowing the sea to encroach on the land and run far inland into the previously made river valleys. This depression probably occurred during the glacial period, perhaps 10,000 years ago, and is an interesting feature of Maine physiography, the embayed coast. To this subidence are due the picturesque coastal scenery, the numerous islands and bays, the good harbours and the peculiar coastal rocks. The shortest distance between the N.E. and the S.W. extremities of the coast is only 225 m.; but, on account of projections and indentations, the coast-line measures not less than 2500 m. The headlands, the deep indentations and the numerous islands, which are cut off by the uplift and subside, and beyond produce a beautiful mingling of land and sea and give to the whole ocean front the appearance of a fringed and tasselled border: west of the mouth of the Kennebec River is a marshy shore and many low gravelly islands; but east of this river the shore becomes more and more bold, rising in the precipitous cliffs and rounded summits of Mt Desert and Quoddy Head, 1527 m., for 1000 ft. high respectively. All along the coast-line there are numerous well-protected harbours, such as Casco, Portland, Frenchman's, Machias and Passamaquoddy bays being especially noteworthy.

After the subside came another period of uplift, possibly still in progress. The glacial erosion has exposed marine deposits of sand, &c., to form little coastal plains at some points along the coast, providing good land for settlement and clay for brick and pottery. Further evidence of this uplift is found in old beach lines now above high water mark.

The principal river systems of Maine are the Saint John on the north slope, and the Penobscot, the Kennebec, the Androscoggin, and the Saco on the south slope. The mean height of the basin of the Saco is 1000 ft. above the sea; of the Penobscot 1900 ft., and of the Saint John 1300 ft. At the junction of this line of mountain streams is the water-parting which divides the state into a north slope and a south slope. The south slope descends gently both to the N. and to the E.; although quite hilly in the lowest portion it is a large upland, covered with swamps and forests.

Flora.—The animal life of Maine shows a mixture of northern and southern forms, and is very little that is peculiar as compared with surrounding regions. The state has moose, caribou and deer, especially in the northern part. The black bear, wolf, catamount, wolverine, wild cat, fox, beaver, raccoon, marten, sable, woodchuck, skunk, otter, mink, rabbit and squirrel are also found. Geeke, ducks and other water fowl frequent the lakes and bays in the migratory season; and there are many song birds, such as robins, lobsiders, clams and scallops {Pecten irradians}; and off the shore are herring, alewives, mackerel, cod, halibut, haddock, smelts, hake, menhaden, porgies and porpoises. The game in the North Woods attracts large numbers of sportsmen during the autumn season.

This condition results from the fact that Maine and the adjacent region were worn down nearly to sea-level by stream erosion, except certain peaks and ridges inland; then the region was elevated and numerous river valleys were cut below the general erosion surface, and the sea sank below the level of the drainage basin of the general ocean. Thus, we have a general "upland surface," above which the mountain remnants tower, and below which the rivers have been entrenched.

This name is applied to a chain of lakes (the Rangeley, or Oquossoc, the Cusapuctic, the Mooselookmeguntic, the Molechunka, the Upper, the Rangeley, the Weld, the Lake, the Long, the Richardson, and the Umbagog) in Franklin and Oxford counties, in the western part of the state; the Umbagog extends into New Hampshire and its outlet helps to form the Androscoggin River. These lakes are connected by short streams, have a total area of between 80 and 90 sq. m., and are from 1200 to 1500 ft. above the sea. They are sometimes called the Androscoggin Lakes.
the south-west border. In 1900 about 21% of the state's area was cleared, and much of the land had been cleared, but not being suited to agriculture had become reforested. Of fruit trees the chief is the apple. The plum, cherry and pear also thrive. The peach grows well along the coast, with the exception of the south-west corner of the state, and the south-east corner is largely cleared, for the climate is cold. The state has a large production of strawberries (1,421,773 bushes of strawberries and 1,066,860 quarts of strawberries in 1899). The output of eggs increased from 9,369,534 dozen in 1889 to 13,304,150 dozen in 1899. The most productive dairy section of the state is the belt extending from the south-west corner N.E. across the state and embracing the counties of Penobscot, Androscoggin, Kennebec, and Aroostook.

Lumber Industry.—Except in the remote parts, the valuable white pine, for which Maine was long noted, has been cut; but the woods of the state afford a large production of timber and other forest products. The state makes large appropriations for preventing and extinguishing forest fires, and in 1903 established a department of forestry in the university of Maine. Good spruce, which is by far the most valuable forest product of the state, is the principal product of the state. The manufacture of paper and pulp, stands in large quantities in the St John, Penobscot, Androscoggin and Kennebec basins. Poplar, also used for the manufacture of paper, abounds in several sections of the state. The manufacture of paper is increasing, and the output of paper has increased from $11,849,654 in 1890 to $12,459,401 in 1900, and to $17,937,683 in 1905.

Agriculture.—The soil is for the most part glacial drift, containing a large mixture of clay with sand or gravel, and the sub-soil is mostly loam, clayey loam, or hardpan. The climate is hard, and for its latitude, cold. Extremes of temperature are not so great as farther inland in the same latitude; for the summer heats are tempered by the sea, and the cool north winds, and the winter cold is so constant as to be less severe than the changing temperature elsewhere in the southern districts. The summers are short, there being only about 42 months between the first frost even in the southern sections, and the mean temperature is about 3° F. The mean winter temperature is about 25° F., and the temperature ranges from 9° to 42° F. The mean temperature of the whole state is 42° F., that for the north slope being about 6° F. less than for the south slope. Although the temperature remains pretty steadily below the freezing point for at least three months of the year, it does the same as much as 10 months in some sections. But, with the exception of those from the west, they are maritime and consequently moisture-bearing. In summer, especially in the latter part of it, the cool and moist N. E. winds often cause a considerable part of the state to be enveloped in fog for several days in succession.

Minerals.—The principal mineral products are granite, limestone, slate, clay products and mineral waters. In 1900 Maine had first rank in the production of granite, the value of the output being $2,713,795. In 1907 Maine's granite was valued at $2,070,397, and that of Massachusetts at $5,448,987. In 1908 the output of granite was valued at $2,713,795. The state has also large deposits of limestone, which are of commercial value. The state is also the chief producer of marble. The marble is of various kinds, the most valuable being the marble of the White Mountains. The state has also large deposits of coal, the chief deposits being in the counties of Penobscot and Aroostook.
tournamaline, spodumene (or kunzite) and beryl occur, the tournamaline crystals being notably large and beautiful. Mineral water occurs in many localities, particularly in Androscoggin, York, Cumberland and Oxford counties; the most famous springs are the Poland Springs in Androscoggin county. Most of the mineral waters bottled in the state are chalybeate and slightly alkaline-saline; their average temperature is about 43°. In 1807, 28 springs were reported, their aggregate sales amounting to 1,182,322 gallons. Copper, lead, and iron are the only minerals of manufacturing, yet the abundance of fine timber and the numerous coves, bays and navigable streams along or near the coast promoted ship-building from the first, and this was the leading industry of the state until about the middle of the 19th century, when in fact the leading industry of the state was manufacturing. Until about the same time, when the Maine liquor law was passed, the manufacture of rum from molasses, received in exchange for lumber and fish in the West Indies, was also an important industry. It was, however, during the 20th century that the rapid use of cement and the river power afforded by the rivers began to be used to any considerable extent. The first cement mill was built at Brunswick on the Androscoggin about 1809, and from 1830 the development of iron and steel manufacturing was rapid; woolen mills followed and in the 19th century were erected some of the largest paper and pulp mills in the country, which are run by water power from the rivers, and use the spruce and poplar timber in the river basins. The largest of these mills produce state that the factory-made products were in 1890, and in 1905 the value of the factory-made products rose to $144,001,977, or 27.8% greater than their value in 1900. Measured by the value of the output of the principal manufacturing industries in 1900, the manufacturing industries of the state ranked second (1890)—$11,849,401 in 1900, and first to 1905; from $3,281,051 in 1890 to $13,223,275 in 1905, an increase of 303% within the decade, and to $22,951,124 in 1905, a further increase of 65% in the period after 1900. In 1905, the value of the factory-made product alone in 1905 was $13,066,690, or 20.1% greater than in 1900. Boots and shoes ranked ninth (1900) and were devalued in 1900; a fact that the value of the factory-made product alone in 1905 was $13,066,690, or 20.1% greater than in 1900. 

The principal railway systems are the Maine Central, which enters every county but one, the Boston & Maine, the Bangor & Aroostook, the Grand Trunk and the Canadian Pacific. Lines of steamboats ply regularly between the largest cities of the state and Boston, between Portland and New York, and between Portland and several Canadian ports.

The foreign trade, especially that with the West Indies and with Great Britain, decreased after 1875, and yet much trade from the West Indies went to New York during the warm months. The exported goods from Maine are: textiles, Indian corn, meat, dairy products, apples, paraffin, boards and shooks; the chief imports from foreign countries are sugar, molasses and wool. Fish, canneled goods, potatoes, granite, lime, paper, and boots and shoes are also exported to foreign countries to some extent, but they are shipped in larger quantities to other states of the Union, from which Maine receives in return, clothing, coal, iron, oil, &c. The principal port of entry in Maine are Bangor, Bath, Belfast, Castine, Eastport, Ellsworth, Houlton, Kennebunk, Machias, Portland, Wiscasset and York.

The population—The population in 1880 was 668,936; in 1890, 669,856; in 1900, 694,466; and in 1910, 743,371. From 1880 to 1900 there was an increase of only 7%, a percentage which was exceeded in every other state in the Union except Nevada and Vermont. Of the total population of 1900, 599,291, or 85.3%, were native whites, 93,330 were foreign-born, 1,319 were negroes, 798 were Indians, 119 were Chinese, and 4 were Japanese. Of the inhabitants born in the United States, 589,211, or 97.8%, were native of New England and 569,506 of the United States, the rest being of foreign birth. The percent of foreign-born, as of the foreign-born, 18,707, or 71.8%, natives of Canada and, the rest being of foreign birth. The percent of foreign-born, as of the foreigners, 1,016,382, or 10.8%, were natives of Ireland. Of the total population, 199,734 were of foreign parentage—i.e. either one or both parents were foreign-born and 89,587 were of Canadian parentage, both on the father’s and on the mother’s side (41,355 English and 48,502 French). The French-speaking inhabitants probably number considerably more than 50,000. They are of two quite distinct classes. One, numbering about 15,000, includes those who became citizens by the establishment of the northern boundary in 1842 and their descendants. They are largely of Acadian stock. The state has established among them a well-appointed training school for teachers, conducted in the English language, the graduates of which render excellent service in the common schools. The other class is of French-Catholic immigrants, who find profitable employment in the manufacturing centers. The colony of Sweden established by the state near its north-eastern border in 1870 has proved a very happy success. The Indians are remnants of the Penobscots and Passamaquoddi tribes. The Penobscots are a little more numerous. The Penobscot chief gathering places are on the islands of the Penobscot river north of Old Town; the Passamaquoddi's, on the shores of Passamaquoddy Bay and the banks of the Saint Croix river.

Roman Catholics are more numerous than all the Protestant sects taken together, having in 1906 a membership of 113,419 out of a total of 212,988 in all denominations. In the last decade of the 19th century the urban population (i.e. population of places having 4,000 inhabitants or more) increased from 226,268 to 251,658, or 11.2%; the semi-urban population (i.e. population of incorporated places, or the approximate equivalent, having less than 4,000 inhabitants) increased from 1,224 to 1,274, or 8.7%; while the rural population (i.e. population outside of incorporated places) decreased from 429,597 to 413,164, or 3.2%. The principal cities of the state are: Portland, pop. (1910), 58,517; Lewiston, 26,247; Bangor, 24,803; Biddeford, 17,079; Auburn, 15,064; Augusta (the capital), 13,211; Water-ville, 11,458; Bath, 9,356; Westbrook, 5,261; and Rockland, 5,174.

The census of 1905 was taken under the direction of the United States census bureau, but the statistics for hand trades were omitted.

1 The census of 1905 was taken under the direction of the United States census bureau, but the statistics for hand trades were omitted.

2 According to previous censuses the population was as follows: (1790) 96,540; (1800) 151,719; (1810) 228,795; (1820) 298,335; (1830) 399,455; (1840) 501,793; (1850) 583,169; (1860) 628,279; (1870) 1,263,626; (1880) 1,535,801; (1890) 1,757,856; (1900) 1,945,216.
September election; or, as provided by an amendment adopted in 1875, the legislature may by a two-thirds vote of each house summon a general convention. From 1819 to 1875 twelve amendments were adopted; in 1875, after nine more were added, the twenty-one were incorporated in the text; and between 1875 and 1890 nine more were adopted. Suffrage is conferred by the constitution on all male citizens of the United States who are at least twenty-one years of age and have, for some other reason than because of being in the military, naval or marine service of the United States, or of being students at college, lived in the state for three months next preceding any election; the following classes, however, are excepted: paupers, persons under guardianship, Indians not taxed, and, as provided by an amendment adopted in 1892, persons intellectually incapable of reading the state constitution in the English language or of writing their names. State elections were annual until 1897 when they were made biennial; they are held on the second Monday in September in even numbered years, Maine being one of the few states in the Union in which they are not held in November.

The governor is the only executive officer of the state elected by popular vote. There is no lieutenant-governor, the president of the Senate being the only other officer in whose election the people have a voice, but there is a council of seven members elected by the legislature (not more than one from any one senatorial district), whose sole function is to advise the governor. The governor's term of office is two years, and he may succeed himself. The constitution further directs that he shall be at least thirty years of age at the beginning of his term, that he shall be a native-born citizen of the United States, that when elected he shall have been a resident of the state for ten years, and that he shall have been a practicing lawyer in the state for six years. His power of appointment is unusually extensive and the advice and consent of the council (instead of that of the Senate in other states) are required for his appointments. He appoints all judges, coroners, and notaries public, all district and city solicitors, and all other officers of the police and fire departments of cities whose electorate neither the constitution nor the laws provide otherwise. The governor is commander-in-chief of the state militia. Any bill of which he disapproves he can within five days after its passage prevent from becoming a law unless it is passed over his veto by a two-thirds vote of each house of the legislature. He and the council examine and pass upon election returns; he may summon extra sessions of the legislature, and he may grant pardons, reprieves, and commutations in all cases except impeachment, but the manner of hearing applications for pardon is in a measure prescribed by statute, and he must present to the legislature an account of each case in which he grants a pardon. His salary is $2,000 a year. In case of his absence from the state, his salary is disbursed to the treasurer, the attorney general and the commissioner of agriculture of the state. The salaries of both are increased biennially by a joint ballot of the two houses of the legislature, which also elects, one every two years, the three state surgeons, whose salary is $600 a year.

The legislature meets biennially at Augusta, the capital, and is composed of a Senate of thirty-one members and a House of Representatives of one hundred and fifty-one members. Members of each house are elected for a term of two years; one senator from each county is elected for a term of three years, and one for a term of six years, a population of 1,500, and seven for a population of 26,250 from each town, or, where the township or plantation has less than 1,500 inhabitants, from each representative district, according to its population in 1821, and every town, city, county, and town-ship, or, where the township or plantation has less than 1,500 inhabitants, from each representative district, according to its population in 1821. Every senator and every representative must at the beginning of his term have been for five years a citizen of the United States, for one year a resident of the state, and for three months a resident of the township or district in which he is elected, and as a resident of the county, city, town-ship, or, where the township or plantation has less than 1,500 inhabitants, from each representative district, according to its population in 1821. Every senator and every representative must be at least twenty-five years of age. All revenue bills must originate in the House of Representatives, but to so originate a bill it must pass both houses and be signed by the governor. Bills that relate solely to raising revenue. Other bills may originate in either house. In September 1908 a constitutional amendment was adopted providing for referendum and initiative by the people. Any bill proposed in the legislature or passed by it must be referred to the people for their approval or rejection. Such a proposition may petition thereof signed by 10,000 voters; and a petition signed by 12,000 voters initiates new legislation.

At the head of the department of justice is the supreme judicial court, which consists of a chief justice and seven associate justices appointed by the governor and council for a term of seven years. When it sits as a law court, at least five of its justices must be present, and it holds three such sessions annually: one at Augusta, one at Bangor, and one at Portland. In cases where one of its judges is required for a trial court, and trial courts are held two or three times a year in each county for the trial of both civil and criminal cases which come before it in the first instance or upon appeal. In Cumberland and Kennebec counties there is a superior court presided over by one justice and having extensive civil and criminal jurisdiction; and in each of the counties there is a probate court for the settlement of the estates of deceased persons and courts of the trial justice and the justice of the peace for the trial of petty offences and of civil cases in which the debt or damage involved does not exceed $20.

Principal forms of local government are the town (or township), the plantation, the county and the city. As in other parts of New England, the town is the most important of these. At the regular town meeting held in March the electorate of the town assembles, decides what shall be done for the town during the ensuing year, how it shall tax itself to meet the expenses, how it shall raise money to meet the expenses, and votes money to meet the expenses. The principal officers are the selectmen (usually three), town clerk, assessors, collector, treasurer, school committee and road commissioner. A census of the town, in order to promote certain financial ends, is commonly incorporated as a village without however becoming a governing organization distinct from the town. Maine is the only state in the Union that retains what is known as the "unincorporated" township having at least 200 inhabitants, and its principal officers are the moderator, clerk, three assessors, treasurer, collector, constable and school committee. The county is the intermediate governing body; and the state, the supreme rule. Maine has no general law under which cities are chartered, and does not even set a minimum population. A town may, therefore, be incorporated as a city whenever it can obtain from the legislature a city charter which its electorate prefers to a continuance under its own government; consequently there is much variety in the government of the various cities of the state.

By the laws of Maine the property rights of a wife are approximately equal to those of a husband. A woman does not lose nor a man acquire right to property by marriage, and a wife may manage, sell, or will her property without the assent of her husband. She may even receive as her own the wages of her personal labour which was not performed for her own family. In the absence of a will, bar or release, there is no legal distinction between the rights of a widower in the estate of his deceased wife and those of a widow in the estate of her deceased husband. The grounds for divorce in the state are adultery, extreme cruelty, desertion for three consecutive years next preceding the application, gross and confirmed habits of intoxication, cruel and abusive treatment, or a husband's gross or wanton refusal or neglect to provide a suitable maintenance for his wife.

Under the laws of Maine a householder owning and occupying a house and lot may hold the same, or such part of it as does not exceed $300 in value, as a homestead exempt from attachment, except for the satisfaction of liens for labour or material, by filing in the registry of deeds a certificate stating his desire for such an exemption, provided he is not the owner of an exempted lot purchased from the state; and the exemption may be continued during the widowhood of his widow or the minority of his children. A considerable amount of personal property, including apparel, household furniture not exceeding $100 in value, a library not exceeding $50 in value, interest in a pew in a meeting-house, and a specified amount of fuel, provisions, tools or farming implements, and domestic animals, and one fishing boat, is also exempt from attachment. The law further provided that the legislature should have power to enact a law for prohibiting the sale of intoxicating liquors. An act for restricting the sale of such liquors was passed in 1846; the first prohibitory act was passed, largely through the influence of Neal Dow, in 1851; this was frequently amended; and in 1884 an amendment 1

1 An unincorporated township containing less than 200 inhabitants may, on the application of three resident voters, be organized as a plantation, but does not pay state or county taxes unless by special legislative order. Other unincorporated districts, especially those along the coast, are called "grants," "surplises," "gores" or "tracts."
to the constitution was adopted which declares the manufacture of intoxicating liquors and their sale, except "for medicinal and mechanical purposes," thus administered by towns and cities. By the law enacted for enforcing this prohibition the governor and council appoint a state liquor commissioner from whom alone the selectmen of a town, the mayor or aldermen of a city, are authorized to receive the liquors which may be sold within the exceptions named in the amendment, and the selectmen, mayor or aldermen appoint an agent who alone is authorized to sell any of these liquors within their jurisdiction and who is forbidden to sell any whatever to minors, Indians, soldiers, and drunkards. But the law labors under the disadvantage of all laws not vigorously sustained by general public sentiment, and is grossly violated. For the most part it is executed to the degree demanded by local sentiment in the several municipalities, thus operating in practice much the same as a "local option" law. The law looks to checking the demand by preventing the supply; and since habitual reliance on the stringency of law tends to the neglect of other influences for the removal of evils from the community, the citizens seem to absolve themselves from personal responsibility, both for the execution of the law and for the existence of the evil itself. There has been a strong movement for the repeal of the law, and the question of prohibition has long been an important one in state politics.

The state was abandoned in Maine in 1876, restored in 1883, and again abolished in 1885.

Penal and Charitable Institutions.—The state penal and reformatory institutions consist of the state prison at Thomaston, the state (reform) school for boys at South Portland, and a state industrial school for girls at New Gloucester. The last named institution was established in the city of Castine in 1866, at Gorham (1879); that at Presque Isle (the Aroostook state normal school, 1903), and the Madawaska training school at Fort Kent, each of which is under the direction of a board of trustees consisting of the governor, the commissioner of education, the superintendent of public instruction, an agent appointed by the governor and council for not more than three years.

At the head of the public school system is the University of Maine, near the village of Orono in Orono township (pop. in 1900, 3257). The charter of the University was adopted in 1868, as the state college of agriculture and the mechanical arts; in 1870 the present name was adopted. It embraces a college of arts and sciences, a college of agriculture, a college of technology (including a department of forestry), a college of law (at Bangor), and a college of medicine (at Augusta). The university was established by the legislature in 1868, and is under the supervision of the Board of Trustees of the University, appointed by the governor and board of public welfare, the last named being elected every three years. The proceeds of an endowment fund derived chiefly from public lands given by the national government in accordance with the land grant, or Morrill, Act of 1862 (see Morrill, Justice S.) and from the bequests ($100,000是韩国 of Jane E. E. Little (1835-1885) and the second Morrill Act (1867), and under the Nebraska Act of 1870, by appropriations of the state legislature, and by fees paid by the students. Connected with the university is an agricultural college, the Maine Agricultural College (1876), established by the Hatch, Act of 1887 and the Adams Act (1906) of the national Congress. The government of the university is entrusted, subject to inspection of the governor and council, to a board of eight trustees. Among the important institutions of higher learning in the state are the Bowdoin College (opened in 1804), at Brunswick; Colby College (Baptist, opened in 1818), at Waterville; and Bates College (originally Free Baptist but now unsectarian; opened in 1853), at Lewiston. In 1900 51% of the state's inhabitants ten years of age and over were illiterate (i.e., could neither read nor write, or could read but not write); of the native whites within this age limit 2.4% were illiterate, of the foreign whites, 19.4%. Of the foreign-born whites 15.7% were unable to speak English.

Finance.—The chief sources of the state's revenue are a general property tax and taxes on the franchises of corporations, especially those of railroad and insurance companies and savings banks; among the smaller sources are licences or fees, a poll tax, and a tax on intangibles. The state auditor, who is appointed by the governor, examines all local revenues of the state and makes a statement of the same. The state auditor also on the first Tuesday in January of every year receives at his office the return of the assessment of the town inspectors of assessors and the outline of the state assessment for the current year; and eight months after the assessment is made returns to the state the outline of the state assessment as it is to be made for the current year. The total assessment of the state for the year 1901 exceeded $6,000,000,000, of which $5,000,000,000 was levied on real estate, and the remainder on personal property, with the exception of the proceeds of the bonds. The assessments are made by the assessors of the several counties, who are appointed by the governor and are required to certify to the state auditor the assessment of the county, together with the assessment of the state. The state auditor returns to the governor a statement of the assessed value of the state for the year, from which the governor issues a warrant for the sum of money required to be levied for the payment of the bonded indebtedness of the state. In the United States, the several states maintain a system of local taxation for the support of public schools, and for the support of such other public duties as may be elected by the town or appointed by the committee, or towns having not less than twenty or more than fifty schools may unite in employing a superintendent. In cities the committee is usually larger than in towns and is commonly elected by wards. Since 1895 no teacher in any town has been employed to furnish text books, apparatus and supplies without the sanction of the selectmen. The minimum length of the school year is fixed by a statute of 1893 at twenty weeks; the average length is about twenty-eight weeks. A compulsory education law, enacted in 1901, requires the attendance of children of the ages of seven and fifteen during all the time that school is in session, except that necessary absences may be excused. For the maintenance of the common schools each town is required (since 1895) to assess a sum of money equal to one-fifth of what may be received from other sources, and to this is added the proceeds of a state tax of one and a half mills on a dollar, one-half the proceeds of the tax on savings banks, a 6% income from the state lands, and a sum of money derived from the proceeds of the sale of state lands, and state appropriations for the payment in part of the superintendence in towns that have united for that purpose. Any section of a town may establish and maintain a high school provide for the state's bonded indebtedness. The bonded debt, however, is rapidly being paid: in January 1901 it was $2,103,000, and in January 1909 only $6,000,000.
History.—During the 16th century and the early part of the 17th, the coast of Maine attracted various explorers, among them Giovanni da Verrazano (1524), Esteban Gomez (1529), Bartholomew Gosnold (1602), Martin Pring (1603), Pierre du Guast, Sieur de Monts (1604), George Weymouth (1605), and John Smith (1614), who explored and mapped the coast and gave to the country the name New England; but no permanent English settlement was established within what are now the borders of the state until some time between 1623 and 1629. In 1603 De Monts received from Henry IV. of France a charter for all the region between 40° and 46° N. under the name of Acadia, or Acadía, and in 1604 he built a fort on Neutral Island at the mouth of the Saint Croix river. This he abandoned in 1605, but some of his followers were in the vicinity a few years later. In the same year George Weymouth explored the southwest coast, kidnapped five Indians, and carried them to England, where three of them lived for a time in the family of Sir Ferdinando Gorges, who soon became the leader in founding Maine. In 1607 the Plymouth Company, of which he was an influential member and which had received a grant of this region from James I. of England in the preceding year, sent out a colony numbering 120 under George Popham (c. 1550-1608), brother of John Popham, and Raleigh Gilbert, son of Sir Humphrey Gilbert. The colony established itself in a river valley that later became Kennebec in August, but, finding its supplies insufficient, about three-fifths of its number returned to England in December; a severe winter followed and Popham died; then Gilbert, who succeeded to the presidency of the council for the colony, became especially interested in his claim to the territory under his father's charter, and in 1608 the colony was abandoned.

In 1609 the French Jesuits Biard and Masse established a fortified mission station on the island of Mount Desert, and although this as well as the remnant of De Monts' settlement at the mouth of the Saint Croix was taken in 1613 by Sir Samuel Argall (d. 1626), acting under the instructions of the English at Jamestown, Virginia, some of these colonists returned later. In 1620 the Council for New England, the successor of the Plymouth Company, obtained a grant of the country between latitude 40° and 48° N. extending from sea to sea, and two years later Gorges and John Mason (1586-1633) received from the Council a grant of the territory between the Merrimac and the Kennebec rivers for 60 m. inland under the name of the Province of Maine. In 1629 they divided their possession, Gorges taking the territory from the Penobscot river to the Kennebec and Mason the country between the Penobscot and the Saco. In 1634 the Council of New England surrendered its charter in 1635. In the division of its territory Gorges retained the portion previously granted to him, and the region between the Kennebec and the Saint Croix north to the Saint Lawrence, though still claimed by the French as part of Acadia, was conveyed to Sir William Alexander (1567-1640); later, in 1664, this was conveyed to the duke of York, afterwards James II. of England.

Gorges named his tract the County of New Somersetshire, and immediately began the administration of government, setting up in 1635 or 1636 a court at Saco under the direction of his kinsman William Gorges. In 1639 he procured for his province a royal charter modeled after that of Maryland, which invested him with the feudal tenure of a county palatine and vice-regal powers of government. He called into existence a formidable large number of officers to govern it, but his charter was in fact impracticable, and after some years he submitted to the Council for New England, east of the Piscataqua; and Gorges and his agents met with a determined opposition under the leadership of George Cleeve, the deputy-president of the Lyonia, or "Plough" Patent, which extended along the coast from Cape Porpoise to Casco, and in issuing which the Council for New England had granted governmental as well as territorial rights. Moreover, Puritan Massachusetts, which was naturally hostile to the Anglicanism of Gorges and his followers, interpreted her charter so as to make her northern boundary run east and west from a point 3 m. north of the source of the Merri- mac river, and on this basis laid claim to practically the whole of Maine then settled. The factional quarrels there, together with the Commonwealth government in England, made it easy for Massachusetts to enforce this claim at the time, and between 1652 and 1658 Maine was gradually annexed to Massachusetts. In 1672 Massachusetts extended her boundary eastward as far as Penobscot Bay. Ferdinando Gorges, a grandson of the original proprietor, brought before parliament his claim to Maine and in 1664 a committee of that body decided in his favor; but Massachusetts successfully resisted until 1677, when the king in council decided against her. She then quietly purchased the Gorges claim for £1,250 and held the province as a proprietor until 1691, when by the new Massachusetts charter Maine was extended to the Saint Croix river, and was made an integral part of Massachusetts.

The French still claimed all territory east of the Penobscot, and not only was Maine an exposed frontier and battleground between the two states of the English and the French but, its citizens bore a conspicuous part in the expeditions beyond its borders. Port Royal was taken in May 1609 by Sir William Phipps and Louisburg in June 1745 by Sir William Pepperell, both these commanders being from Maine. These expeditions were such a drain on Maine's population that Massachusetts was called upon to send men to garrison the little forts that protected the homes left defenseless by men who had gone to the front. During the War of Independence, the town of Falmouth (now Portland), which had ardently resisted the claims of the British, was bombarded and burned, in 1775; in the same year Benedict Arnold followed the course of the Kennebec and Dead rivers on his expedition to Quebec; and from 1779 to 1783 a British force was established at Castine. The embargo and non-intercourse laws from 1807 to 1812 were a severe blow to Maine's shipping, and in the War of 1812 Eastport, Castine, Hampden, Bangor and Machias fell into the hands of the British.

Maine was in general well governed as a part of Massachusetts, but a geographical separation, a desire to be rid of the burden of a separate debt, and a difference of economic interest as well as of politics (Maine was largely Democratic and Massachusetts was largely Federalist) created a desire for an independent commonwealth. This was felt before the close of the War of Independence and in 1785-1787 conventions were held at Falmouth (Portland) to consider the matter, but the opposition prevailed. The want of protection during the War of 1812 revived the question, and in 1816 the General Court in response to a great number of petitions submitted to a vote in the towns and plantations of the District the question: "Shall the legislature be requested to give its consent to the separation of the District of Maine from Massachusetts, and the erection of said District into a separate state?" The returns showed 10,393 yeas to 6501 nays, but they also showed that less than one-half the full vote had been cast. Acting upon these returns the legislature passed a bill prescribing the terms of separation, and directed another vote of the towns and plantations upon the question of separation and the election of delegates to a convention at Brunswick which should proceed to frame a constitution in case the second popular vote gave a majority of five to ten for separation; but as that vote fell by 11,060 in favor of those opposed to separation, the advocates of separation were unsuccessful. But a large source of opposition to separation was removed in 1819 when Congress, dividing the east coast of the United States into two great districts, did away with the regulation which, making each state a district for entering and clearing vessels, would have required coating vessels from the ports of Maine as a separate state to enter and clear on every trip to or from Boston; as a consequence, the separation measures were carried.

1 By this charter, issued in 1578, Sir Humphrey Gilbert was entitled to all territory lying within two hundred leagues of any colony that he might plant within six years; although it had long since lapsed, Raleigh Gilbert seems not to have been aware of it.
MAINE

by large majorities this year, a constitution was framed by a
congression which met at Portland in October, this was ratified
by two conventions in December, and Maine applied for admis-
sion into the Union. Owing to the peculiar situation at the
time in Congress, arising from the contest over the admission
of Missouri, the question of the admission of Maine became
an important one in national politics. By an Act of the 3rd of
March 1820, however, Maine was finally admitted into the
Union as a separate state, her admission being a part of the
Missouri compromise.

The boundary on the north had not yet been ascertained,
and it had long been a subject of dispute between the United
States and Great Britain. The treaty of 1783 (Article II.)
had defined the north-east boundary of the United States as extend-
ing along the middle of the river St Croix "from its mouth in
the bay of Fundy to its source " and "due north from the source
of St Croix river to the highlands; along the said highlands which
divide those rivers that empty themselves into the river St
Lawrence from those which fall into the Atlantic Ocean, to the
north-westernmost head of Connecticut river; thence down
along the middle of that river to the forty-fifth degree of north
latitude, and thence east along that line to the Grand Mere
highlands; and thence south along the Grand Mere highway
and the northerly line was 140 m. long, running to highlands
dividing the Ristigouche and the tributaries of the Metis; and there
was a further disagreement with regard to the side of the high-
lands on which the boundary should be, and as to what stream was
the "north-westernmost head of Connecticut river."

The fifth article of the Jay treaty of 1794 provided for a com-
misson to decide what the St Croix river actually was, and this
commission in 1798 defined the St Croix, saying that its mouth
was in Passamaquoddy bay and that the boundary ran up this
river and the Chepuntateook to a marked monument. The
commission at Ghent in 1814 (Article IV.) referred the question
of the ownership of the islands in Passamaquoddy bay to a com-
misson which gave Moose, Dudley and Frederick islands to
the United States; and the same treaty by Article V. provided
for the survey (which was made in 1817-1818) of a part of the
disputed territory, and declared that the disputed line was
the westernmost head of the river St Croix; and that the line met at
St Andrews, N.B., in 1816, and in New York City in 1820, only to
disagree; and when the king of the Netherlands, chosen as arbitrator in 1829 (under
the Convention of 1827), rendered in 1831 a decision against which
the state of Maine protested, the Federal Senate withheld its
assent to his decision. In 1838-1839 the territory in dispute
between New Brunswick and Maine became the scene of a border
"war," known as the "Aroostook disturbance;" Maine erected
forts along the line she claimed, Congress authorized the president
to resist any attempt of Great Britain to enforce exclusive
jurisdiction over the disputed territory, and an armed conflict
seemed imminent. General Winfield Scott was sent to take
command on the Maine frontier, and on the 21st of March 1839
he arranged a truce and a joint occupancy of the territory in
dispute until a satisfactory settlement should be reached by
the United States and Great Britain. The Webster-Ashburton
treaty of 1842 was a compromise, which allowed Maine about
5500 sq. m. less than she had claimed and allowed Great Britain
about as much less than her claim; all grants of land previously
made by either party within the limits of the territory which
by this treaty fell within the dominions of the other party were
to be "held valid, ratified and confirmed to the persons in
possession under such grants, to the same extent as if such
territory had ... fallen within the dominions of the party
by whom such grants were made; " and the government of the
United States agreed to pay to Maine and Massachusetts1 "in
an Article in the Act relating to the separation of Maine from
Massachusetts stipulated that the lands within the District of Maine
which prior to the separation had belonged to Massachusetts should
after the separation belong one-half to Maine and one-half to Mas-
sachusetts. In 1826 the wild lands of Maine were surveyed and
divided between the two states; and in 1833 Maine acquired from
the sum of $300,000 as compensation for the
lands which they had claimed and which under the treaty they
were entitled to surrender. The long controversy, which is
known in American history as "The North-East boundary
dispute," was not finally settled however until 1910.

It was the Democratic majority in the district of Maine that
affected the separation from Massachusetts, and from the date
of that separation until 1853 Maine was classed as a Democratic
state, although it elected a Whig governor in 1853 and in 1840,
and cast its electoral vote for John Quincy Adams in 1824 and
1828 and for W. H. Harrison in 1840. As a result of the slavery
question, there was a party disintegration between 1850 and
1855, followed by the supremacy of the Republican party from
1856 to 1878. In 1878, of the 126,169 votes cast in the election
for governor, Selden Connor (b. 1839), re-nominated by the
Republicans, received 66,554; Joseph L. Smith ("National" or
"Greenback"), 41,371; Alonzo Garconel (1813-1906) (Demo-
cratic), 28,218; as no candidate received a majority of the votes,
the election was left to the legislature. The vote of the House
eliminated Connor, and Garconel was chosen in the Senate by
a Democratic-National Fusion. Again there was no election
by popular vote in 1879, and Garconel and his council, to secure
the Supreme Court decision, courted a fusion majority, which
did not exist in the legislature by evident falsification of the returns.
On the 3rd of January 1880 the Supreme Court declared
the governor and council in error in counting in a fusion majority,
but on the 7th the governor swore in a legislature with 78 fusion
and only two Republican members, and, the governor's term
having expired, the president of the Senate, James D. Lamson,
became governor, ex-officio. On the 12th the legislative
chambers were seized by the Republicans, whose organized
legislature was declared legal by the Supreme Court, and
who chose as governor Daniel Franklin Davis (1845-1897); where-
on, on the 17th, Joshua L. Chamberlain, to whom the peaceful
solution of the difficulty had largely been due, retired from the
task assigned him by Garconel on the 5th of January "to protect
the public property and institutions of the state" until Garconel's
successor should be duly qualified. In 1880 the Democrats
and Greenbacks united and elected their candidate, but after
1853 Maine was strongly Republican until 1910.

The governors of the state have been as follows:

Massachusetts, for $362,500, all of this land still remaining in posses-
sion of the latter state.

1 According to Art. V. of the constitution a majority of the total
number of votes cast was required for election; in case no candidate
should receive a majority, it was prescribed that the "House of
Representatives shall, by ballot, from the persons having the four
highest numbers of votes on the lists, if so many there be, elect two
persons and make returns of their names to the Senate, of whom the
Senate shall, by ballot, elect one, who shall be declared the governor."
MAINE DE BIRAN—MAINE-ET-LOIRE

MAINE DE BIRAN, FRANÇOIS-PIERRE-GONTIER (1706-1814). French philosopher, was born at Bergerac, on the 29th of November 1706. The name Maine he assumed (some time before 1787) from the estate called Le Maine, near Mouleydier. After studying with distinction under the d’arbours of Early Péguy, he entered the life-guards of Louis XVI., and was present at Versailles on the memorable 5th and 6th of October 1789. On the breaking up of the garde du corps Biran retired to his paternal inheritance of Grateloup, near Bergerac, where his retired life preserved him from the horrors of the Revolution. It was at this period that, to use his own words, he “passed per salutum from frivolity to philosophy.” He began with psychology, which he made the study of his life. After the Reign of Terror Maine de Biran took part in political affairs. Having been excluded from the council of the Five Hundred on suspicion of royalism, he took part with his friend Lanhé in the commission of 1813, which gave expression for the first time to direct opposition to the will of the emperor. After the Restoration he held the office of treasurer to the chamber of deputies, and habitually retired during the autumn recess to his native district to pursue his favourite study. He died on the 30th (16th, or 12th, according to others) of July 1824.

Maine de Biran’s philosophical reputation has suffered from two causes—his obscure and laboured style, and the fact that only a few, and these the least characteristic, of his writings appeared during his lifetime. These consisted of the essay habit (Sur l’influence de l’habitude, 1803), a critical review of P. Lamariguier’s lectures (1817), and the philosophical portion of the article “Leibnitz” in the Biographie universelle (1819). A treatise on the analysis of thought (Sur la décomposition de la pensée), although sent to press, was never printed. In 1834 these writings, together with the essay entitled considérations sur les rapports du physique et du moral de l’homme, were published by Victor Cousin, who in 1841 added three volumes, under the title Essais philosophiques de Maine de Biran. But the publication (in 1859) by E. Naville (from MSS. placed at his father’s disposal by Biran’s son) of the Essais inédits de Maine de Biran, in three volumes, first rendered possible a connected view of his philosophical development. At first a sensualist, like Condillac and Locke, next an intellectualist, he finally shows himself a mystical theosophist. The

Essais sur les fondements de la psychologie represents the second or most complete stage of his philosophy, the fragments of the Nouveaux essais d’anthropologie the third.

Maine de Biran’s philosophy were written avowedly from the point of view of Locke and Condillac, but even in them he was brought to signalize the essential fact on which his later speculation turns. Dealing with the formation of habits, he is compelled to note that past passions after transformed, do not furnish a complete or adequate explanation thereof, in which he distinguishes attention as an active effort, of no less importance than the passive receptivity of sense, and with Butler distinguishes passively formed customs from active habits. He finally arrived at the conclusion that Condillac’s habit theory of perception was not only an error in fact but an error of method—in short, that the mechanical mode of view did not distinguish the conscious from the unconscious, which arise in dealing with conscious experience, such as the mode by which the organism is cognized, the mode by which the organism is distinguished from extra-organic things, and the nature of those general laws by which the relations of things are known to us—cause, force, &c.

In the latest stage of his speculation Biran distinguishes the animal existence from the human, under which he includes the forms above pointed out, and classes the latter, the spirit, in which human thought is brought into relation with the animal, a divine system of things. This stage is left imperfect. Altogether Biran’s work presents a very remarkable specimen of deep metaphysical thinking directed by preference to the psychological aspect of experience.

The Essais inédits de Maine de Biran by E. Naville contain an introductory study; in 1887 appeared Science et psychologie; nouvelles considérations sur les rapports du physique et du moral de l’homme. See also O. Truman in Cornell Studies in Philosophy, No. 5 (1904) on Maine de Biran’s Philosophy of Will.

MAINE-ET-LOIRE, a department of western France, formed in 1790 for the most part out of the southern portion of the former province of Anjou, and bounded N. by the departments of Mayenne and Sarthe, E. by Indre-et-Loire, S.E. by Vienne, S. by Deux-Sèvres and Vendée, W. by Loire-Inférieure, and N.W. by Ille-et-Vilaine. Area, 2756 sq. m. Pop. (1906), 513,490. Maine-et-Loire is made up of two distinct regions, the line of demarcation running roughly from north to south along the valley of the Sarthe, then turning south-west and passing Brissac and Doué; that to the west consists of granites, felspars, and a continuation of the geological formations of Brittany and Vendée; to the east, schists, limestone and chalk prevail. The department is a transition from south-west to the majestic valley of the Loire, with its rich orchards, vineyards, and market-gardens. The highest altitudes are found in the north of the department, where north-east of Cholet one eminence reaches 689 ft. Elsewhere the surface is low and undulating in character. The department belongs entirely to the basin of the Loire, the bed of which is wide but shallow, and full of islands, the depth of the water in summer being at some places little more than 2 ft. Floods are sudden and destructive. The chief affluent of the Loire within the department is the Maine, formed a little above Angers by the junction of the Mayenne and the Sarthe, the latter having previously received the waters of the Loire. All three are navigable. Other tributaries of the Loire are the Thouet (with its tributary the Dive), the Layon, the Eyre, and the Dive at the left, and the Authon on the right. The Maine is joined on the right by the Oudon, which can be navigated below Segré. The Erdre, which joins the Loire at Nantes, and the Maine, a tributary of the Sèvre-Nantaise, both rise
within this department. The climate is very mild. The mean annual temperature of Angers is about 53°, slightly exceeding that of Paris; the rainfall (between 24 and 24 in annually) is distinctly lower than that of the rest of France. Notwithstanding this deficiency, the frequent fogs, combined with the peculiar nature of the soil in the south-east of the department, produce a degree of moisture which is highly favourable to meadow growths. The winter colds are never severe, and readily permit the cultivation of certain trees which cannot be reared in the adjoining departments.

The agriculture of the department is very prosperous. The produce of cereals, chiefly wheat, oats and barley, is in excess of its needs, and potatoes and mangels also give good returns. Extensive areas in the valley of the Loire are under hemp, and the vegetables, melons and other fruits of that region are of the finest quality. Good wine is produced at Serrant and other places near Angers, and on the right bank of the Layon and near Saumur, the sparkling white wine of which is a rival of the cheaper brands of champagne. Cider is also produced, and the cultivation of fruit is general. Forests and woodland in which oak and beech are the chief trees cover large tracts. The fattening of cattle is an important industry round Cholet, and horses much used for light cavalry are reared. Several thousand workmen are employed in the slate quarries in the vicinity of Angers, tufa is worked in the river valleys, and freestone and other stone, mispickel, iron and coal are also found. Cholet, the chief industrial town, and its district manufacture pocket-handkerchiefs, as well as linen clothes, flannels, cotton goods, and hempen and other coarse fabrics, and similar industries are carried on at Angers, which also manufactures liqueurs, rope, boots and shoes and parasols. Saumur, besides its production of wine, makes beads and enamels. The commerce of Maine-et-Loire comprises the exportation of live stock and of the various products of its soil and industries, and the importation of hemp, cotton, and other raw materials. The department is served by the railways of the state and the Orleans and Western companies. The Mayenne, the Sarthe and the Loir, together with some of the lesser rivers, provide about 1,500 m. of navigable waterway. In the south-east the canal of the Dine covers some 10 m. in the department.

There are five arrondisements—Angers, Baugé, Cholet, Saumur and Segré, with 34 cantons and 381 communes. Maine-et-Loire belongs to the académie (educational division) of Rennes, to the region of the VIII. army corps, and to the ecclesiastical province of Tours. Angers (q.v.), the capital, is the seat of a bishopric and of a court of appeal. Other principal places are Cholet, Saumur, and Fontevrault, which receive separate treatment. For architectural interest there may also be mentioned the châteaux of Brissac (17th century), Serrant (15th and 16th centuries), Montreuil-Bellay (14th and 15th centuries), and Ecuillé (15th century), and the churches of Puy-Notre-Dame (13th century) and St Florent-le-Vieil (13th, 17th, and 19th centuries), the last containing the finest monument to Charles Emmanuel, Duke of Savoy. In the department of Maine-et-Loire there remains of a theatre and other ruins of the Roman period, as well as two churches dating in part from the 10th century. Ponts-de-Cé, an interesting old town built partly on islands in the Loire, is historically important, because till the Revolution its bridges formed the only way across the Loire between Saumur and Nantes.

MAINPURI, or MUNPOOBE, a town and district of British India, in the Agra division of the United Provinces. The town has a station on a branch of the East Indian railway recently opened from Shikohabad. Pop. (1901), 19,000. It consists of two separate portions, Mainpuri proper and Mukhamanganj. Holkar plundered and burned part of the town in 1804, but was repulsed by the local militia. Since the British occupation the population has rapidly increased and many improvements have been carried out. The Aggra branch of the Grand Trunk road runs through the town, forming a wide street lined on both sides by shops, which constitute the principal bazaar. Mainpuri has a speciality in the production of carved wooden articles inlaid with brass wire. The American Presbyterian mission manages a high school.

The district of Mainpuri lies in the central Doab. Area, 1,673 sq. m. Pop. (1901), 829,537, an increase of 8.8% in the decade. It consists of an almost unbroken plain, flooded by small rivers, with a few undulating sand ridges. It is wooded throughout with mango groves, and isolated clumps of bāleul trees occasionally relieve the barreness of its saline ussār plains. On the south-western boundary the Jumna flows in a deep alluvial bed, sometimes sweeping close to the high banks which overhang its valley, and elsewhere leaving room for a narrow strip of fertile soil between the river and the upland plain. From the low-lying lands thus formed a belt of ravines stretches inland for some 2 m., often covered with jungle, but affording good pasturage for cattle. The district is watered by two branches of the Ganges canal, and is traversed by the main line of the East Indian railway.

Mainpuri anciendly formed part of the great kingdom of Kanauj, and the fall of that famous state was divided into a number of petty principalities, of which Rapri and Bhongao were the chief. In 1194 Rapri was made the seat of a Moslem governor. Mainpuri fell to the Moguls on Baber’s invasion in 1526, and, although temporarily recovered from them, fell to the short-lived Afghan dynasty of Shere Shāh, was again occupied by them in the beginning of the 18th century. After the victory of Panipat. Like the rest of the lower Doab, Mainpuri passed, towards the end of the 18th century, into the hands of the Marathas, and finally became a portion of the province of Oudh, which, from 1801 to 1856, was a British possession. In 1856 the district was divided in two, and placed under a British governor. In 1861, the town became the headquarters of the eastern division of Etawah, which was in 1856 reduced by the formation of Etah and Mainpuri into separate collectorates. On the outbreak of the Afghan war in 1878, Mainpuri revolted and attacked the town, which was successfully defended by the few Europeans of the station for a week, until the arrival of the Janshi mutineers made it necessary to abandon the district.

MAINTENANCE (Fr. maintenance, from manter, to main-
tain, support, Lat. manu tenere, to hold in the hand). The action of giving support, supplying means of subsistence, keeping efficient or in working order. In English law maintenance is an officious intermeddling in an action that in no way belongs to one by maintaining or assisting either party, with money or otherwise, to prosecute or defend it. It is an indefensible offence, both at common law and by statute, and punishable by fine and imprisonment. It invalidates all contracts involving it. It is also actionable. There are, however, certain cases in which maintenance is justifiable, e.g. any one who has an interest, even if it be only contingent, in the matter at variance can maintain another in an action concerning the matter; or several parties who have a common interest in the same thing may maintain one another in a suit concerning the same. Neither is it reckoned maintenance to assist another in his suit on charitable grounds, or for a master to assist his servant, or a parent his son, or a husband his wife. The law with regard to the subject is considered at length in Bradlaugh v. Needegate, 1883, 11 Q.B.D. 1. See also CHAMPERTY. For the practice of "livery and mainten-
ance" see ENGLISH HISTORY, §§ v. and vi.

A CAP OF MAINTENANCE, i.e. a cap of crimson velvet turned up with golden plate, is borne, as one of the insignia of the British sovereign, immediately before him at his coronation or on such state occasions as the opening of parliament. It is carried by the hereditary bearer, the marquess of Winchester, upon a white wand. A similar cap was also borne before the lord mayor of London. The origin of this symbol of dignity is obscure. It is stated in the New English Dictionary that it was granted by the pope to Henry VII. and Henry VIII. It is probably connected with the "cap of estate" or "cap of beneficence," sometimes similar to the royal symbol with two peaks or horns behind, which is borne as a heraldic charge by certain families. It seems originally to have been a privilege of dukes. Where it is used the crest is placed upon it, instead of on the usual wreath.

MAINTENON, FRANÇOISE D’AUBIGNÉ, MARQUISE DE (1635–1719), the second wife of Louis XIV., was born in a prison at Niort, on the 7th of November 1635. Her father, Constant d’Aubigné, was the son of Agrippa d’Aubigné, the famous friend and general of Henry IV., and had been imprisoned as a Huguenot malcontent, but her mother, a fervent Catholic, had the child...
baptized in her religion, her sponsors being the duc de la Rochefoucauld, father of the author of the Maxims, and the comtesse de Neuillant. In 1639 Constant d'Aubigné was released from prison and took all his family with him to Martinique, where he died in 1645, after having lost what fortune remained to him at cards. Mme d'Aubigné returned to France, and from sheer poverty unwillingly yielded her daughter to her sister-in-law, Mme de Villette, who made the child very happy, but converted or pretended to convert her to Protestantism. When this was known an order of state was issued that she should be entrusted to Mme de Neuillant, her godmother. Every means was now used to convert her back to Catholicism, but at the last she only yielded on the condition that she need not believe that the soul of Mme de Villette was lost. Once reconverted, she was neglected and sent home to live with her mother, who had only a small pension of 200 livres a year, which ceased on her death in 1650. The chevalier de Meré, a man of some literary distinction, who had made her acquaintance at Mme de Neuillant's, discovered her penniless condition, and introduced his "young Indian," as he called her, to Scarron, the famous wit and comic writer, at whose house all the literary society of the day assembled. Scarron took her to be his companion and secretaire, and applied for her admission to a convenant, or, though he was deformed and an invalid, to marry her himself. She accepted his offer of marriage, and became Mme Scarron in 1651. For nine years she was not only his most faithful nurse, but an attraction to his house, where she tried to bridle the licence of the conversation of the time. On the death of Scarron, in 1660, Anne of Austria continued his pension to his widow, and even increased it to 2000 livres a year, which enabled her to entertain and frequent the literary society her husband had made her acquainted with; but on the queen-mother's death in 1666 the king refused to continue her pension, and she prepared to leave Paris for Lisbon as lady attendant to the queen of Portugal. But before she started she met Mme de Montespan, who was already, though not avowedly, the king's mistresse, and who took such a fancy to her that she obtained the continuance of her pension, which put off for ever the question of going to Portugal. Mme de Montespan did yet more for her, for when, in 1666, her first child by the king was born, Mme Scarron was established with a large income and a large staff of servants at Vaugirard to bring up the king's children in secrecy as they were born. In 1674 the king determined to have his children at court, and their governess, who had now made sufficient fortune to buy the estate of Maintenon, accompanied them. The king had now many opportunities of seeing Mme Scarron, and, though at first he was prejudiced against her, her even temper contrasted so advantageously with the storms of passion and jealousy exhibited by Mme de Montespan, that she grew steadily in his favour, and had in 1678 the gratification of having her estate at Maintenon raised to a marquisate and herself entitled Mme de Maintenon by the king. Such favours brought down the fury of Mme de Montespan's jealousy, and Mme de Maintenon's position was almost unendurable, until, in 1680, the king severed her connexion by making the latter second lady in waiting to the dauphiness, and soon after Mme de Montespan left the court. The new amie used her influence on the side of decency, and the queen openly declared she had never been so well treated as at this time since her marriage to the king, at Maintenon's arms in 1658. The queen's death opened the way to yet greater advancement; in 1684 Mme de Maintenon was made first lady in waiting to the dauphiness, and in the winter of 1685-1686 she was privately married to the king by Harlay, archbishop of Paris, in the presence, it is believed, of Père la Chaise, the king's confessor, the marquis de Montchevreuil, the chevalier de Forbin, and Bontemps. No written proof of the marriage is extant, but that it took place is nevertheless certain. Her life during the next thirty years can be fully studied in her letters, of which many authentic examples are extant. As a wife she was wholly admirable; she had to entertain a man who would not be amused, and had to submit to that terribly strict court etiquette of absolute obedience to the king's inclination, which Saint-Simon so vividly describes, and yet be always cheerful and never complain of weariness or ill-health. Her political influence has probably been exaggerated, but it was supreme in matters of detail. The ministers of the day used to discuss and arrange all the business to be done with the king beforehand with her, and it was all done in her cabinet and in her presence, but the king in more important matters often chose not to consult her. Such mistakes as, for instance, the replacing of Catinat by Villeroi may be attributed to her, but not whole policies—notably, according to Saint-Simon, not the policy with regard to the Spanish succession. Even the revocation of the edict of Nantes and the dragonnades have been laid to her charge, but recent investigations have tended to show that in spite of ardent Catholicism, she at least opposed, if not very vigorously, the cruelties of the dragonnades, although she was pleased with the conversions they procured. She was apparently afraid to imperil her great reputation for devotion, which had in 1692 obtained for her from Innocent XII. the right of visitation over all the convents in France. Where she deserves blame is in her use of her power for personal patronage, as in compassing the promotions of Chamillart and Villeroi, and the frequent assistance given to her friends. Her influence was on the whole a moderating and prudent force. Her social influence was not as great as it might have been, owing to her holding no recognized position at court, but it was always exercised on the side of decency and morality, and it must not be forgotten that from her former life she was intimate with the literary people of the day. Side by side with this public life, which wearied her with its shadowy power, occasionally crossed by a desire to be recognised as queen, she passed a nobler and sweeter private existence as the foundress of St Cyr. Mme de Maintenon was a born teacher; she had so won the hearts of her first pupils that they preferred her to their own mother, and was similarly successful later with the young and impetuous duchess of Burgundy, and she had always wished to establish a home for poor girls of good family placed in such straits as she herself had experienced. As soon as her fortunes began to mend she started a small home for poor girls at Rueil, which she afterwards moved to Noisy, and which was the nucleus of the splendid institution of St Cyr, which the king endowed in 1686, at her request, out of the dues of the Abbey of St Denis. She was in her element there. She herself drew up the rules of the institution; she examined every minute detail; she befriended her pupils in every way; and her heart often turned from the weariness of Versailles or of Marly to her "little girls" at St Cyr. It was for them that Racine wrote his Esther and his Athalie, and it was because he managed the affairs of St Cyr well that Michel Chamillart became controller-general of the finances. The later years of her power were marked by the promotion of her old pupils, the children of the king and Mme de Montespan, to high dignity between the blood royal and the peers of the realm, and it was doubtless under the influence of her dislike for the duke of Orleans that the king drew up his will, leaving the personal care of his successor to the duke of Maine, and hampering the duke of Orleans by a council of regency. Or even before her husband's death she retired to St Cyr, and had the chagrin of seeing all her plans for the advancement of the duke of Maine overthrown by means of the partition of 1715. The duchesse de Maine, by marriage made heir-presumptive to the throne, on the contrary, visited her at St Cyr and continued her pension of 48,000 livres. She spent her last years at St Cyr in perfect seclusion, but an object of great interest to all visitors to France, who, however, with the exception of Peter the Great, found it impossible to get an audience with her. On the 15th of April 1719 she died, and was buried in the choir at St Cyr, bequeathing her estate at Maintenon to her niece, the only daughter of her brother Charles and wife of the maréchal de Noailles, to whose family it still belongs. 

L. A. la Beaumelle published the Lettres de Madame de Maintenon, but much garbled, in 2 vols. in 1752, and on a larger scale in 9 vols. in 1756. He also, in 1755, published Mémoires de Madame de Maintenon, in 6 vols., which caused him to be imprisoned in the Bastille. All earlier biographies were superseded by Théophile Lavallée's Histoire de St Cyr, reviewed in Causeries du lundi, vol. viii., and by his edition of her Lettres historiques et édifiantes, &c., in 7 vols.
MAINZ

The site of Mainz would seem to mark it out naturally as a great centre of trade, but the illiberal rule of the archbishop and its military importance seriously hampered its commercial and industrial development, and prevented it from rivalling its neighbour, Frankfurt. It is now, however, the chief emporium of the Rhinen wine traffic, and also carries on an extensive transit trade in grain, timber, flour, petroleum, paper and vegetables. The natural facilities for carriage by water are supplemented by the extensive railway system. Large new harbours to the north of the city were opened in 1887. The principal manufactures are leather goods, furniture, carriages, chemicals, musical instruments and carpets, for the first two of which the city has attained a wide reputation. Other industries include brewing and printing.

Mainz is the seat of the administrative and judicial authorities of the province of Rhein-Hessen, and also of a Roman Catholic bishop.

History.—Mainz, one of the oldest cities in Germany, was originally a Celtic settlement. Its strategic importance was early recognized by the Romans, and about 13 B.C. Drusus, the son-in-law of Augustus, erected a fortified camp here, to which the castellum Maietiacorum (the modern Castel) on the opposite bank was afterwards added, the two being connected with a bridge at the opening of the Christian era. The Celtic name became latinized as Magnutiacum, or Moguntiacum, and with a town gradually arose around the camp, which became the capital of Germania Superior. During the Völkerwanderung Mainz suffered severely, being destroyed on different occasions by the Alamanni, the Vandals and the Huns. Christianity seems to have been introduced into the town at a very early period, and in the 6th century a new Mainz was founded by Bishop Sidonius. In the middle of the 8th century under Boniface it became an archbishopric, and to this the primacy of Germany was soon annexed. Charlemagne, who had a palace in the neighbourhood, gave privileges to Mainz, which rose rapidly in wealth and importance, becoming a free city in 1118. During the later middle ages it was the seat of several diets, that of 1384 being of unusual size and splendour. In 1388 it was seized against Archbishop Arnold, and in 1163 the walls of the city were pulled down by order of the emperor Frederick I. But these events did not retard its progress. In 1244 certain rights of self-government were given to the citizens; and in 1254 Mainz was the centre and mainspring of a powerful league of Rhinen towns. Owing to its commercial prosperity it was known as goldene Mainz, and its population is believed to have been as great as it is at the present day. But soon a decline set in. In 1462 there was warfare between two rival archbishops, Diether or Dietrich II. of Isenburg (d. 1463) and Adolph II. of Nassau (d. 1475). The citizens espoused the cause of Diether, but their city was captured by Adolph; it was then deprived of its privileges and was made subject to the archbishop. Many of the inhabitants were driven into exile, and these carried into other lands a knowledge of the art of printing, which had been invented at Mainz by Johann Gutenberg in 1450. During the Thirty Years' War Mainz was occupied by the Swedes in 1631 and by the French in 1644, the fortifications were strengthened by the latter. In 1688 it was captured again by the French, but they were driven out in the following year. In 1792 the citizens welcomed the ideas of the French Revolution; they expelled their archbishop, Friedrich Karl Joseph d'Erthal, and opened their gates to the French troops. Taken and retaken several times during the next few years, Mainz was ceded to France by the treaty of Campo Formio in 1797, and again by the Treaty of Lunéville in 1801. In 1814 it was restored to Germany and it was handed over to the grand duke of Hesse; it remained, however, a fortress of the German confederation and was garrisoned by Prussian and Austrian troops. Since 1871 it has been a fortress of the German Empire. There were disturbances in the city in 1848.

See Brühl, Mainz, geschichtlich, topographisch und malerisch (Mainz, 1829); C. A. Schaal, Geschichte der Stadt Mainz (Mainz, 1851); K. von Meinecke, Mainz und seine Umgebungen (1868); C. G. Bockenheimer, Beiträge zur Geschichte der Stadt Mainz (1874); Neeb, Führer durch Mainz und Umgebung (Stuttgart, 1903); and O. Beck, Mains und sein Handel (Mainz, 1881).
The Archbishops of Mainz, one of the seven ecclesiastical electors of the Holy Roman Empire, became a powerful state during the middle ages and retained some of its importance until the disolution of the empire in 1806. Its archbishop was president of the electoral college, arch-chancellor of the empire and primate of Germany. Its origin dates back to 747, when the city of Mainz was made the seat of an archbishop, and a succession of able and ambitious prelates, obtaining lands and privileges from emperors and others, made of the district under their rule a strong and vigorous state. Among these men were Hatto I. (d. 913), Siegfried III. of Eppstein (d. 1249), Gerhard of Eppstein (d. 1309), and Albert of Brandenburg (d. 1345), all of whom played important parts in the history of Germany. There were several violent contests between rivals anxious to secure so splendid a position as the electorate, and the pretensions of the archbishops occasionally moved the citizens of Mainz to revolt. The lands of the electorate lay around Mainz, and were on both banks of the Rhine; their area at the time of the French Revolucion was about 3200 sq. m. The last elector was Karl Theodor von Dalberg. The archbishopric was secularized in 1803, two years after the lands on the left bank of the Rhine had been seized by France. Some of those on the right bank of the river were given to Prussia and to Hesse; others were formed into a grand duchy for Dalberg. The archbishopric itself was transferred to Regensburg.

For the history of the electorate see the Scriptores rerum magnaticarum, edited by G. C. Joannis (Frankfort, 1722–1727); Schunk, Beitrag zur Mainzer Geschichte (Frankfort, 1788–1791); Hennes, Die Erzbischöfe von Mainz (Mainz, 1879); P. J. Jalle, Monumenta moguntina (Berlin, 1866), and J. F. Böhmer and C. Will, Regesta archiepiscoporum moguntinensium (Innsbruck, 1877–1886).

Mairet, Jean De (1604–1686). French dramatist, was born at Besançon, and baptized on the 10th of May 1604. His own baptismal name was born in 1613, and went to Paris to study at the Collège des Grassins about 1625, in which year he produced his first piece Christi et Arimand, followed in 1626 by Sylvie, a “pastoral tragi-comedy.” In 1634 appeared his masterpiece, Sophonisbe, which, in its observance of the rules, the beginning of the “regular” tragedies. Mairet was one of the bitterest assailants of Corneille in the controversy over The Cid. It was perhaps his jealousy of Corneille that made him give up writing for the stage. He was appointed in 1648 official representative of the Franche-Comté in Paris, but in 1653 he was banished by Mazarin. He was subsequently allowed to return, but in 1668 he retired to Besançon, where he died on the 31st of January 1686. His other plays include Silvainre ou la Morte-vive, published in 1631 with an elaborate preface on the observance of the unities, Les Galanteries du duc d’Orsonne (1652), Virginie (1653), Marc-Antoine (1653), and Le Grand et dernier Solyman (1657).

See G. Bize, Étude sur la vie et les œuvres de Jean de Mairet (1877). Sophonisbe was edited by K. Vollmöller (Heilbronn, 1868), and Silvainre by R. Otto (Bamberg, 1890).

Mairet, Joseph De (1754–1821). French diplomatist and polemical writer, was born at Cambray on the 1st of April 1754. His family was an ancient and noble one, everyone the title of count, and is said to have been of Languedocien extraction. The father of Joseph was president of the senate of Savoy, and held other important offices. Joseph himself, after studying at Turin, received various appointments in the civil service of Savoy, finally becoming a member of the senate. In 1786 he married Françoise de Morand. The invasion and annexation of Savoy by the French Republicans made him an exile. He did not take refuge in that part of the king of Sardinia’s domains which was for the time spared, but betook himself to the as yet neutral territory of Lausanne. There, in 1796, he published his first important work (he had previously written certain discourses, pamphlets, letters, &c.), Considerations la France. In this he developed his views, which were those of a Legitimist, but a Legitimist entirely from the religious and Roman Catholic point of view. The philosophism of the 18th century was Joseph de Maistre’s lifelong object of assault.

After the still further losses which, in the year of the publication of this book, the French Revolution inflicted on Sardinia, Charles Emmanuel summoned Joseph de Maistre to Turin, and he remained there for the brief space during which the king retained a remnant of territory on the mainland. Then he went to the island of Sardinia, and held office at Cagliari. In 1802 he was appointed envoy extraordinary and minister plenipotentiary at St. Petersburg, and journeyed thither the next year. Although his post was no sinecure, its duties were naturally less engrossing than the official life, with intervals of uneasy exile and travelling, which he had hitherto known, and his literary activity was great. He only published a single treatise, on the Principe générateur des Constitutions; but he wrote his best and most famous works, Du Pape, De L’Église gallicane et les Soirées de St. Pétersbourg, the last of which was never finished. Du Pape, which the second-named book completes, is a treatise in regular form, dealing with the relations of the sovereign pontiff to the Church, to temporal sovereigns, to civilization generally, and to schismatics, especially Anglicans and the Greek Church. It is written from the highest possible standpoint of papal absolutism. The Soirées de St. Pétersbourg, so far as it is anything (for the arrangement is somewhat desultory), is a kind of théodicee, dealing with the fortunes of virtue and vice in this world. It contains two of De Maistre’s most famous pieces, his panegyric on the executioner as the foundation of social order, and his acrimonious, and in part unfair, but also in part very damaging, attack on Locke. The Du Pape is dated May 1817; on the Soirées the author was still engaged at his death. Besides these works he wrote an examination of the philosophy of Bacon, some letters on the Inquisition (an institution which, as may be guessed from the remarks just noticed about the executioner, was no stumbling-block to him), and, earlier than any of these, a translation of Plutarch’s “Essay on the Delay of Divine Justice,” with somewhat copious notes. After 1815 he returned to Savoy, and was appointed to high office, while his Du Pape made a great sensation. But the world to which he had returned was not altogether in accordance with his desires. He had domestic troubles; and chagrin of one sort and another is said to have been not a little to do with his death by paralysis on the 26th of February 1821 at Turin. Most of the works mentioned were not published till after his death, and it was not till 1851 that a collection of Lettres et opuscules appeared, while even since that time fresh matter has been published.

Joseph de Maistre was one of the most powerful, and by far the ablest, of the leaders of the neo-Catholic and anti-revolutionary movement. The most remarkable thing about his standpoint is that, layman as he was, it was entirely ecclesiastical. Unlike his contemporary Bonald, Joseph de Maistre regarded the temporal monarchy as an institution of altogether inferior importance to the spiritual primacy of the pope. He was by no means a political absolutist, except in so far as he regarded obedience as the first of political virtues, and he seldom loses an opportunity of stipulating for a tempered monarchy. But the pope’s power is not to be tempered at all, either by councils or by the temporal power or by national churches, least of all by private judgment. The peculiarity of Joseph de Maistre is that he supports his conclusions, or if it be preferred his paradoxes, by the hardest and heaviest argument. Although a great master of rhetoric, he never makes rhetoric do duty for logic. Every now and then it is possible to detect fallacies in him, but for the most part he has succeeded in carrying matters back to those fundamental differences of opinion which hardly admit of argument, and on which men take sides in consequence chiefly of natural bent, and of predilection for one state of things rather than for another. The absolute necessity of order may be said to have been the first principle of this thinker, who, in more ways than one, will invite comparison with Hobbes. He could not conceive such order without a single visible authority, reference to which should settle all dispute. He saw that there could be no such temporal head, and in the pope he thought that he saw a spiritual substitute. The anarchic tendencies of the Revolution in politics and religion were what offended him. It ought to be
added that he was profoundly and accurately learned in history and philosophy, and that the superficial blunders of the 18th-century philosophers irritated him as much as their doctrines. To Voltaire in particular he shows no mercy.

Of the two works named as his masterpieces, Du Pape and the Soirées de St. Petersbourg, editions are extremely numerous. No complete edition of his works appeared till 1884-1887, when one was published at Lyons in 14 volumes. This had been preceded, and has been followed, by numerous biographies and discussions: C. B. Mommsen, L'oeuvre de Maistre (1889); R. de Sèvres, Joseph de Maistre (1865), and J. C. Glaser, Graf Joseph Maistre (same year); L. I. Moreau, Joseph de Maistre (1879); F. Paulhan, Joseph de Maistre et sa philosophie (1893); L. Cogordan, Joseph de Maistre, in the Grandes écrivains français (1894); P. Dusssett, Joseph de Maistre avant la révolution (1896), and other works by the same writer; J. Mandoul, Un Homme d'état italien: Joseph de Maistre et la politique de la maison de Savoie (1900); and E. Grasset, Joseph de Maistre (1901). (G. Sa.)

MAISTRE, XAVIER DE (1763-1852), younger brother of Joseph de Maistre, was born at Chambéry in October 1763. He served when young in the Piedmontese army, and wrote his delightful fantasy, Voyage autour de ma chambre (published 1794) when he was at Turin. In consequence of Xavier shared the politics and the loyalty of his brother, and on the annexation of Savoy to France, he left the service, and took a commission in the Russian army. He served under Suvarov in his victorious Austro-Russian campaign and accompanied the marshal to Russia. He shared the disgrace of his general, and supported himself for some time in St. Petersburg by miniature painting. But on his brother's arrival in St. Petersburg he was introduced to the minister of marine. He was appointed to several posts in the capital, but also saw active service, was wounded in the Caucasus, and attained the rank of major-general. He married a Russian lady and established himself in his adopted country, even after the overthrow of Napoleon, and the consequent restoration of the Piedmontese dynasty. For a time, however, he lived at Naples, but he returned to St. Petersburg and died there on the 12th of June 1852. He was only once in Paris (in 1839), when Sainte-Beuve, who has left some pleasant reminiscences of his brother, observed that Xavier de Maistre's works (all of which are of very modest dimensions) are Le Lépreux de la cité d'Aoste (1811), a touching little story of human misfortunes; Les Prisonniers du Casaque, a powerful sketch of Russian character, La Jeune Sibérienne, and the Expédition nocturne, a sequel to the Voyage autour de ma chambre (1825). His style is of remarkable ease and purity.

His works, with the exception of some brief chemical tracts, are included in the collections of Charpentier, Garnier, &c. See Sainte-Beuve's Portraits contemporains, vol. iii.

MAITLAND, EDWARD (1824-1897), English humanist writer, was born at Ipswich on the 27th of October 1824, and was educated at Caius College, Cambridge. The son of Charles David Maitland, perpetual curate of St. James's Chapel, Brighton, he was educated for the Church, but his religious views did not permit his taking holy orders. For some years he lived abroad, in Italy and California, and then the commission of Crownlands in Australia. After his return to England in 1857 he took up an advanced humanitarian position, and claimed to have acquired a new sense by which he was able to discern the spiritual condition of other people. He was associated with Mrs. Anna Kingsford (1846-1888), the lady-doctor and supporter of vegetarianism and anti-vivisectionism, who, besides being one of the pioneers of higher education for women, had become a devotee of mystical theosophy; with her he brought out Keys of the Croeds (1875), The Perfect Way: or the Finding of Christ (1882), and founded the Hermetic Society in 1884. After her death he founded the Esoteric Christian Union in 1891, and wrote her Life and Letters (1896). He died on the 2nd of October 1897.

MAITLAND, FREDERIC WILLIAM (1832-1906), English jurist and historian, son of John Gorham Maitland, was born on the 28th of May 1830, and educated at Eton and Trinity, Cambridge, being bracketed at the head of the moral sciences tripos of 1872, and winning a Whewell scholarship for International law. He was called to the bar (Lincoln's Inn) in 1876, and made himself a thoroughly competent equity lawyer and conveyancer, but finally devoted himself to comparative jurisprudence and especially the history of English law. In 1884 he was appointed reader in English law at Cambridge, and in 1888 became Downing professor of the laws of England. Though handicapped in his later years by delicate health, his intellectual grasp and wide knowledge and research gradually made him famous as a jurist and historian. He edited numerous volumes for the Selden Society, including Select Pleas for the Crown, 1200-1225; Select Pleas in Manorial Courts and The Court Baron; and among his principal works were Gloucester Pleas (1884), Justice and Police (1885), Bracton's Note-Book (1887), History of English Law (with Sir F. Pollock, 1895; new ed. 1898; see also his article ENGLISH LAW in this encyclopedia), Domesday Book and Beyond (1897), Township and Borough (1898), Canon Law in England (1898), English Law and the Renaissance (1901), the Life of Leslie Stephen (1906), besides important contributions to the Cambridge Modern History, the English Historical Review, the Law Quarterly Review, Harvard Law Review and other publications. His writings are marked by vigour and vitality of style, as well as by the highest qualities of the historian who recreates the past from the original sources; he had no sympathy with either legal or historical pedantry; and his death at Grand Canary on the 9th of December 1906 deprived English law and letters of one of their most scholarly and most inspiring representatives, notable alike for sweetness of character, acuteness in criticism, and wisdom in counsel.

See P. Vinogradoff's article on Maitland in the English Historical Review (1907); Sir F. Pollock's in the Quarterly Review (1907); G. T. Lapsey's in The Law Bag (Boston, Mass., 1907); A. L. Smith, F. Pollock and F. H. Maitland (1910).

MAITLAND, SIR RICHARD (LORD LETHINGTON) (1496-1586), Scottish lawyer, poet, and collector of Scottish verse, was born in 1496. His father, Sir William Maitland of Lethington and Thirlstane, fell at Flodden; his mother was a daughter of George, Lord Seton. He studied law at the university of St. Andrews, and afterwards in Paris. His castle at Lethington was burnt by the English in 1540. He was in 1552 one of the commissioners to settle matters with the English about the debatable lands. About 1561 he seems to have lost his sight, but this did not render him incapable of attending to public business, as he was the same year admitted an ordinary lord of session with the title of Lord Lethington, and a member of the privy council; and in 1562 he was appointed keeper of the Great Seal. He resigned this last office in 1567, in favour of John, prior of Coldingham, his second son, but he sat on the bench till he attained his eighty-eighth year. He died on the 20th of March 1586. His eldest son, by his wife Mary Cranston of Crosbie, was William Maitland (q.v.); his second son, John (c. 1545-1595), was a lord of session, and bore the title of Lord Maitland of Thirlstane, in which he was succeeded by his son, John, also for some time a lord of session, who was created Earl of Lauderdale in 1624. One of Sir Richard's daughters, Margaret, assisted her father in preparing his collection of old Scots verse.

The poems of Sir Richard Maitland, none of them lengthy, are for the most part satirical, and are principally directed against the social and political abuses of his time. He is chiefly remembered as the industrial collector and preserver of many pieces of Scots poetry. These were copied into two large volumes, one in folio and another in quarto, the former written by himself, and the latter by his daughter. After being in the possession of his descendant the duke of Lauderdale, these volumes were purchased at the sale of the duke's library by Samuel Pepys, and have since been preserved in the Pepysian Library, Magdalene College, Cambridge. They lay there unnoticed for many years till Bishop Percy published one of the poems in his Reliques of English Poetry. Several of the
prices were then transcribed by John Pinkerton, who afterwards published them under the title of Ancient Scottish Poems (2 vols., 1863).

For an account of the Maitland Folio MS. see Gregory Smith's Specimens of Middle Scots, 1902 (p. lxxiii.). The Scottish Text Society has undertaken an edition of the entire manuscript. Maitland's own poems were reprinted by Sibbald in his Chronicles of Scottish Poetry, and in the Maitland Club, named after him, and founded for the purpose of continuing his efforts to preserve the remains of early Scots literature. Sir Richard left in manuscript a history of the family of Seton, and a volume of legal decisions, dated by him between the years 1550 and 1565. Both are preserved in the Advocates' Library, Edinburgh; the former was published by the Maitland Club, in 1829.

Maitland (Maitland of Lethington), William (c. 1528–1573), Scottish statesman, eldest son of the preceding, was educated at St. Andrews. At an early age he entered public life and began in various ways to serve the regent, Mary of Lorraine, becoming her secretary of state in 1558. In 1559, however, he deserted her and threw in his lot with the lords of the congregation, to whom his knowledge of foreign, and especially of English, politics, and his general ability were assets of the highest value. The lords put him in the Maitland Club. Engaged to ask for assistance from Elizabeth, and his constant aim throughout his political career was to bring about a union between the two crowns. He appears to have feared the return of Mary Queen of Scots to Scotland, but after her arrival in 1561 he was appointed secretary of state, and for about six years he directed the policy of Scotland and enjoyed the confidence of the queen. His principal antagonist was John Knox; there were several tussles between them, the most famous, perhaps, being the one in the general assembly of 1564, and on the whole Maitland held his own against the preachers. He was doubtless concerned in the conspiracy against David Rizzio, and after the favourite's murder he was obliged to leave the court and was himself in danger of assassination. In 1567, however, he was again at Mary's side. He was a consenting party to the murder of Darnley, although he had favoured his marriage with Mary, but the enmity between Bothwell and himself was one of the reasons which drove him into the arms of the queen's successor, whose favour he figured at Langside. He was one of the Scots who met Elizabeth's representatives at York in 1568; here he showed a desire to exculpate Mary and to marry her to the duke of Norfolk, a course of action probably dictated by a desire to avoid all revelations about the Darnley murder. But this did not prevent him from being arrested in September 1569 on account of his share in the crime. He was, however, delivered from his captors by a ruse on the part of his friend, Sir William Kirkcaldy of Grange, and was brought into Edinburgh Castle, while his trial was put off because the city was thronged with his adherents. Maitland now became the leader of the remnant which stood by the cause of the imprisoned queen. Already a physical wreck, he was borne into Edinburgh Castle in April 1751 and with Kirkcaldy he held this fortress against the regent Morton and his English auxiliaries. The castle surrendered in May 1573 and on the 7th or 9th of June following he was thrown down at Leith, there being very little evidence for the theory that he poisoned himself. "Secrecy Maitland" was a man of great learning with a ready wit and a caustic tongue. He was reputed to be the most versatile and accomplished statesman of his age, and almost alone among his Scottish contemporaries he placed his country above the claims of either the Roman Catholic or the Protestant religions. Among the testimonies to his great abilities are those of Queen Elizabeth, of William Cecil and of Knox. By his second wife, Mary Fleming, one of Queen Mary's ladies, whom he married in 1567, he had a son and daughter. His son James died without issue about 1620.

See John Skelton, Maitland of Lethington (1894); A. Lang, History of Scotland, vol. ii. (1902).

Maitland, East and West, adjoining municipalities in Northumberland county, New South Wales, Australia, 110 m. by rail N. of Sydney. Pop. (1901), West Maitland, 6798; East Maitland, 3287. These towns are situated in a valley on the Hunter River, which is liable to sudden floods, to guard against which the river is protected by stone embankments at West Maitland, while there are flood-gates at East Maitland. Maitland is the centre of the rich agricultural district of the Hunter valley, which produces maize, wheat and other cereals, lucerne, tobacco, fruit and wine; excellent coal is also worked in the vicinity. East Maitland is the see of a Roman Catholic bishop, whose cathedral (St. John's), however, is situated in the larger town. Besides this, West Maitland contains several handsome public and private buildings.

Maitreya, the name of the future Buddha. In one of the works included in the Pali canon, the Digha Nikāya, a prophecy is put into the Buddha's mouth that after the decay of the religion another Buddha, named Metteyya, will arise who will have thousands of followers instead of the hundreds that the historical Buddha had. This is the only mention of the future Buddha in the canon. For some centuries we hear nothing more about him. But when, in the period just before and after the Christian era, some Buddhists began to write in Sanskrit instead of Pali, they composed new works in which Maitreya (the Sanskrit form of Metteyya) is more often mentioned, and details are given as to his birthplace and history. These are entirely devised in imitation of the details of the life of the historical Buddha, and have no independent value. Only the names differ. The document in which the original prophecy occurred was put together at some date during the 1st century after the Buddha's death (see NIKĀYA). It is impossible to say whether tradition was, at that time, correct in attributing it to the Buddha. But whoever chose the name (it is a patronymic or family, not a personal name), had no doubt regard to the etymological connexion with the word for "love," which is Mettā in Pali. This would only be one of those punning allusions so frequent in Indian literature.

Long afterwards, probably in the 6th or 7th century, a reformer in South India, at a time when the incoming flood of ritualism and superstition threatened to overwhelm the simple teaching of the earlier Buddhism, wrote a Pali poem, entitled the Anāgārika-Vansa. In this he described the golden age of the future when, in the time of Metteyya, kings, ministers and people would live one with the other in the maintenance of the original simple doctrine, and in the restoration of the good times of old. The other side also claimed the authority of the future Buddha for their innovations. Statues of Maitreya are found in Buddhist temples, of all sects, at the present day; and the belief in his future advent is universal among Buddhists.

Maiwand, a village of Afghanistan, 50 m. N.W. of Kandahar. It is chiefly notable for the defeat inflicted on a British brigade under General Burrows by Ayub Khan on the 27th of July 1880 during the second Afghan War (see Afghanistan). Ayub Khan, Shere Ali's cousin, who had been holding Herat during the British operations at Kandahar, set out towards Kandahar with a small army in June 1880, and a brigade under General Burrows was detached from Kandahar to oppose him. Burrows advanced to the Helmund, opposite Girishk, to oppose Ayub Khan, but was there deserted by the troops of Shere Ali, the wali of Kandahar, and forced to retreat to Kushki-n-Nakhud, half way to Kandahar. In order to prevent Ayub passing to Ghazni, Burrows advanced to Maiwand on the 27th of July, and attacked Ayub, who had already seized that place. The Afghans, who numbered 25,000 outflanked the British, the artillery expended their ammunition, and the native portion of the Brigade got out of hand and pressed back on the few British infantry. The British were
completely routed, and had to thank the apathy of the Afghans for escaping total annihilation. Of the 2476 British troops engaged, 934 were killed and 175 wounded or missing. This defeat necessitated Sir Frederick Roberts' famous march from Kabul to Kandahar.

See Lord Roberts, Forty-one Years in India (1896).

**MAIZE**, or INDIAN CORN, *Zea Mays* (from *ζέα* or *ζεά*, which appears to have been "spelt," *Triticum spelta*, according to the description of Theophrastus), a plant of the tribe Maydeae of the order Gramineae or grasses (see fig. 1). It is unknown in the native state, but is most probably indigenous to tropical America. Small grains of an unknown variety have been found in the ancient tombs of Peru, and Darwin found heads of maize embedded on the shore in Peru at 85 ft. above the present sea-level. Bonausous, however (Histoire naturelle du maïs), quotes authorities (Bock, 1532, Ruel and Fuchs) as believing that it came from Asia, and maize was said by Santa Rosa de Viterbo to have been brought by the Arabs into Spain in the 13th century. A drawing of maize is also given by Bonausous from a Chinese work on natural history, Li-chi-chin, dated 1562, a little over sixty years after the discovery of the New World.

It is not figured on Egyptian monuments, nor was any mention made of it by Eastern travellers in Africa or Asia prior to the 16th century. Humboldt, Alphonse de Candolle and others, however, do not hesitate to say that it originated solely in America, where it had been long and extensively cultivated at the period of the discovery of the New World; and that is the generally accepted modern view. Some hold the view that maize originated from a common Mexican fodder grass, *Euchlaena mexicana*, known as Teosinte, a closely allied plant which when crossed with maize yields a maize-like hybrid.

The plant is monocious, producing the staminate (male) flowers in a large feathery panicle at the summit, and the (female) dense spikes of flowers, or "cobs," in the axils of the leaves below, the long pink styles hanging out like a silken tassel. They are invested by the sheaths of leaves, much used in packing oranges in south Europe, and the more delicate ones for cigarettes in South America. Fig. 2 shows a branch of the terminal male inflorescence. Fig. 3 is a single spikelet of the same, containing two florets, with the three stamens of one only protruded. Fig. 4 is a spike of the female inflorescence, protected by the sheaths of leaves—the blades being also present. Usually the sheaths terminate in a point, the blades being arrested. Fig. 5 is a spikelet of the female inflorescence, consisting of two outer glumes, the lower one ciliated, which enclose two florets—one (a) barren (sometimes fertile), consisting of a flowering glume and pale only, and the other (b) fertile, containing the pistil with elongated style. The mass of styles from the whole spike is everted from the summit of the sheaths, as in fig. 4. Fig. 6 shows the fruit or grain. More than three hundred varieties are known, which differ more among themselves than those of any other cereal. Some come to maturity in two months, others require seven months; some are as many feet high as others are inches; some have kernels eleven times larger than others. They vary similarly in shape and size of ears, colour of the grain, which may be white, yellow, purple, striped, &c., and also in physical characters and chemical composition. Dr E. Lewis Sturtevant, who has made an extended study of the forms and varieties, classes into seven groups those grown primarily for the grain, the distinguishing characters of which are based on the grains or kernels; there are, in addition, forms of horticultural interest grown for ornament. Pod corn (var. *tunicata*) is characterized by having each kernel enclosed in a husk. Pop corn (var. *everta*) has a very large proportion of the "endosperm"—the nutritious matter which with the small embryo makes up the grain—of a horny consistency, which causes the grain to pop when heated, that is to say, the kernel becomes turned inside out by the explosion of the contained moisture. It is also characterized by the small size of the grain and ear. Flint
MAJESTY—MAJLÁTH

449

The colour of the grain varies greatly, being generally white, yellow, mottled red, or less commonly red. Soft corn (var. amyloaceae) has no horny endosperm, and hence the grains shrink uniformly. It is cultivated only to a limited extent in the United States, but seems to have been commonly grown by the Indians in many localities in North and South America. Sweet corn (var. saccharata) is characterized by the translucent horny appearance of the grains and their more or less wrinkled condition. It is pre-eminently a garden vegetable, the ear being used before the grain hardens, when it is well filled but soft and milky. It is often cooked and served in the cob; when canned it is cut from the cob. Canned sweet corn is an important article of domestic commerce in America and the United States. In starchy sweet corn (var. amyloa-saccharata) the grain has the external appearance of sweet corn, but examination shows the lower half to be starchy, the upper horny and translucent. A form of flint corn, with variegated leaves, is grown for ornament under the name Zea japonica or Japanese striped corn.

Chemical analysis, like common experience, shows that Indian corn is a very nutritious article of food, being richer in albuminoids than any other cereals when ripe (calculated in the dry weight). It can be grown in the tropics from the level of the sea to a height equal to that of the Pyrenees and in the south and middle of Europe, but it cannot be grown in England with any chance of profit, except perhaps as fodder. Frost kills the plant in all its stages and all its varieties; and the crop does not flourish well if the nights are cool, no matter how favourable the other conditions. Consequently it is the first crop to disappear as one ascends into the mountain regions, and comparatively little is grown west of the great plains of North America. In Britain, where it scarcely ripens the grain, it furnishes a strong crop in the autumn upon sandy soil where clover and lucerne will yield but a poor produce. It prefers a deep, rich, warm, dry and mellow soil, and hence the rich bottoms and fertile prairies of the Mississippi basin constitute the region of its greatest production. It is extensively grown throughout India, both for the ripe grain and for use of the unripe cob as a green vegetable. It is the most common crop throughout South Africa, where it is known as mealies, being the staple food of the natives. It is also largely used for fodder and is an important article of export.

As an article of food maize is one of the most extensively used grains in the world. Although commonly in Germany and fat, it does not make good bread. A mixture of rye and corn meal, however, makes an excellent coarse bread, formerly much used in the Atlantic states, and a similar bread is now the chief coarse bread of Portugal and some parts of Spain. It is either baked into cakes, called tortilla by the Indians of Yucatan, or made into a kind of porridge, as in Ireland. When deprived of the gluten it constitutes oswego, maizena or corn flour. Maize contains more oil than any other cereal, ranging from 3.5 to 9.5% in the commercial grain. This is one of the factors in its use for fattening purposes. In distilling and some other processes this oil is separated and forms an article of commerce. When maize is sown broadcast or closely planted in drills the ears may not develop at all, but the stalk is richer in sugar and sweeter; and this is the basis of growing "corn-fodder." The amount of forage that may be produced in this way is enormous; 50,000 to 80,000 lb. of green corn are grown per acre, which makes 5000 to 12,000 lb. as field-cured. Sugar and molasses have from time to time been manufactured from the corn stalks.

See articles on corn and Zea Mays in L. H. Bailey’s Cyclopedia of American Agriculture (1900-1902); and for cultivation in India, Watt’s Dictionary of the Economic Products of India, vi. (1893).

MAJESTY (Fr. majesté; Lat. majestas, grandeur, greatness, from the base mag-, as in magus, great, major, greater, &c.), dignity, greatness, a term especially used to express the dignity and power of a sovereign. This application is to be traced to the use of majestas in Latin to express the supreme sovereignty of the Roman state, the majestas reipublicae or populi Romani, hence majestatem laedere or minuere, was to commit high treason, crimen majestatis. (For the modern law and usage of laesa majestas, ile majesté, Majestätsbelägerung, see TREASON.) From the republic majestas was transferred to the emperors, and the majestas populi Romani became the majestas imperii, and augustalis majestas is used as a term to express the sovereign person of the emperor. Honorius and Theodosius speak of themselves in the first person as nostra majestas. The term "majesty" was strictly confined in the middle ages to the successors of the Roman emperors in the West, and was also reserved for the emperor Charles V. Later the word is used of kings also, and the distinction is made between imperial majesty (caesarina majestas) and kingly or royal majesty. From the 16th century dates the application of "Most Christian and Catholic Majesty" to the kings of France, of "Catholic Majesty" to the kings of Spain, of "Most Faithful Majesty" to the kings of Portugal, and "Apostolic Majesty" to the kings of Hungary. In England the use is generally assigned to the reign of Henry VIII., but it is found, though not in general usage, earlier; thus the New English Dictionary quotes from an Address of the Kings Clerks to Henry II. in 1171 (Materials for the History of Archbishop Becket, vii. 471, Rolls Series, 1883), where the king is styled vresta majestas, and Selden (Titles of Honour, part i. ch. 7. p. 98. ed. 1672) finds many early uses in letters to Edward I., in charters of creation of peers, &c. The fullest form in English usage is "His Most Gracious Majesty"; another form is "The King’s Most Excellent Majesty," as in the English Prayer-book. "His Sacred Majesty" was common in the 17th century; and of this form Selden says: "It is true, I think, that in our memory or the memory of our fathers, the use of it first began in England.

"His Majesty," abbreviated H. M., is now the universal European use in speaking of any reigning king, and "His Imperial Majesty," H. I. M., of any reigning emperor.

From the particular and very early use of "majesty" for the glory and splendour of God, the term has been used in ecclesiastical art of the representation of God the Father enthroned in glory, sometimes with the other persons of the Trinity, and of the Saeculum, enthroned with an aureole.

MAJLÁTH, JÁNOS, OR JOHN, COUNT (1786-1853), Hungarian historian and poet, was born at Pest on the 5th of October 1786. First educated at home, he subsequently studied philosophy at Eger (Ger.), and law at the Universities of Pest and Tubingen. He became (1817) a friend of Joseph Majlath, an Austrian minister of state, eventually obtaining for him an appointment in the public service. Majlath devoted himself to historical research and the translation into German of Magyar folk-tales, and of selections from the works of the best of his country’s native poets. Moreover, as an original lyrical writer, and as an editor and adapter of old German poems, Majláth showed considerable talent. During the greater part of his life he resided either at Pest or Vienna, but a few years before his death he removed to Munich, where he fell into a state of destitution and extreme despondency. Seized at last by a terrible infatuation, he and his daughter Henriette, who had long been his constant companion and amanuensis, drowned themselves in the Lake of Starnberg, a few miles south-west of Munich, on the 3rd of January 1835.

Of his historical works the most important are the Geschichte der Magyaren (Vienna, 1828-1831, 5 vols.; 2nd ed., Ratisbon, 1852-1853) and his Geschichte des österreichischen Kaiserstaats (Hamburg, 1834-1835, 2 vols.). Especially noteworthy among his more special publications from the Hungarian are the Magyarsche Geschichte (Stuttgart and Tubingen, 1825); and Himyfö’s auserlesne Liesebeslied (Pest, 1829; 2nd ed., 1831). A valuable contribution to folk-lore appeared in the Magyarsche Sagen, Märchen und Erzählungen (Brünn, 1825; 2nd ed., Stuttgart and Tubingen, 1837, 2 vols.).
MAJOLICA, a name properly applied to a species of Italian ware in which the body is coated with a tin-enamel, on which is laid and fired a painted decoration. It is also applied to similar wares made in imitation of the Italian ware in other countries. The word in Italian is majolica. Du Cange (Gloss, s.v. "Majorica") quotes from a chronicle of Verona of 1368, in which the form majolica occurs for the more usual Latin form majorica. It has usually been supposed that this type of pottery was first made in the island of Majorca, but it is more probable that the name was given by the Italians to the lustred Spanish ware imported by ships hailing from the Balearic Islands. (See CERAMICS: Medieval and Later Italian.)

MAJOR (or MAIR), JOHN (1470-1530), Scottish theological and historical writer, was born at the village of Gieghorne, near North Berwick, Scotland, in the year 1470. He was educated at the school of Haddington, where John Knox was later a pupil. After a short period spent at Cambridge (at God's House, afterwards Christ's College) he entered the university of Paris in 1493, studying successively at the colleges of St Barbe, Montaigu and Navarre, and graduating as a master of arts in 1496. Promoted to the doctorate in 1505, he lectured on philosophy at Montaigu College and on theology at Navarre. He visited Scotland in 1515 and returned in 1518, when he was appointed principal regent in the university of Glasgow, John Knox being among the number of those who attended his lectures there. In 1522 he removed to St Andrew's University, where in 1525 George Buchanan was one of his pupils. He returned to the college of Montaigu in 1525, but was once more at St Andrew's in 1531, where he was head of St Salvator's College from 1534 until his death.

Major's voluminous writings may be grouped under (a) logic and philosophy, (b) Scripture commentary, and (c) history. All are in Latin, all appeared between 1503 and 1530, and all were printed in Paris. The first was his Epistola de Moribus (1502); his commentary on Petrus Hispanus (1504-1505), his Inclitorum artem libri (1506, &c.), his commentary on Joannes Dup (1504, &c.), his Insolubilia (1516, &c.), his introduction to Aristotle's logic (1521, &c.), his commentary on the ethics (1530), and, chief of all, his commentary on Peter Lombard's Sentences (1509, &c.); the second consists of a commentary on Matthew (1518) and another on the Four Gospels (1520); the last is represented by his famous Historia Majoris Britanniae tam Anglicae quam Scotiae per J. M. (1521). In political philosophy he maintained the Scottish civil authority was derived from the popular will, but in theology he was a scholastic conservative, though he never failed to show his approbation of Gallicanism and its plea for the reform of ecclesiastical abuses. He has left on record that it was his aim and hope to reconcile realism and nominalism in the interests of theological peace. He had a world-wide reputation as a teacher and writer. Buchanan's severe epigram, perhaps the only unfriendly words in the flood of contemporary praise, may be explained as a protest against the compromise which Major appeared to offer rather than as a personal attack on his teacher. Major takes a more independent attitude in his History, which is a remarkable example of historical accuracy and insight. He claims that the historian's chief duty is to write truthfully, and he is careful to show that a theologian may fulfil this condition.

The History, on his fame now rests, was reprinted by Freebain (Edinburgh, 1740), and was translated in 1802 by Archibald Constable for the Scottish History Society. The latter volume contains a full account of the author by Aeneas J. G. Mackay and a bibliography by Thomas Graves Lawe.

MAJOR (Lat. for "greater"); a word used, both as a substantive and adjective, for that which is greater than another in size, quality, degree, importance, &c., often opposed correlatively to this in which it is equal. In the categorical syllogism in logic, the major term is the term which forms the predicate of the conclusion, the major premise is that which contains the major term. (For the distinction between major and minor intervals, and other applications in music, see Music and Harmony.)

The use of Major as part of an official title in Med. Lat. has given the Span. mayor, Fr. maire, and Eng. "mayor" (q.v.). In English the unadapted form "major" is the title of a military officer now ranking between a captain and a lieutenant-colonel. Originally the word was used adjectively in the title "sergeant-major," an officer of high rank (third in command of an army) who performed the same duties of administration, drill and encampments on the staff of the chief commander as the sergeant in a company performs as assistant to the captain. This was in the latter half of the 16th century, and very-soon afterwards the "sergeant-major" became known as the "sergeant-major-general"—hence the modern title of major-general. By the time of the English Civil War "majors" had been introduced in each regiment of foot, who corresponded in a lesser sphere to the "major-general" of the whole army. The major's sphere of duties, precedence and title have since varied but little, though he has, in the British service, taken the place of the lieutenanthonel-colonel as second in command—the latter officer exercising the command of the cavalry regiment, infantry battalion or artillery brigade, and the colonel being, save for certain administrative functions, little more than the titular chief of his regiment. Junior majors command companies of infantry; squadrons of cavalry and batteries of artillery are also commanded by majors. In most European armies, however, and of late years in the army of the United States also, the major has become a battalion commander under the orders of a regimental commander (colonel or lieutenant-colonel). The word appears also in the British service in "brigade-major" (the adjutant or staff officer of a brigade). "Town-majors" (garrison staff officers) are now no longer appointed. In the French service up to 1871 the "major-general" was the chief of the general staff of a field army, and thus preserved the tradition of the former "sergeant-major" or "sergeant-major-general." MAJORCA (Mallorca), the largest of the group of Spanish islands in the Mediterranean Sea known as the Balearic Islands (q.v.). Pop. (1900), 248,191; area, 430 sq. m. Majorca has the shape of a trapezoid, with the angles directed to the cardinal points; and its diagonal, from Cape Grozer in the west to Cape Pera in the east, is about 60 m. On the north-west the coast is precipitous, but on the other sides it is low and sloping. On the north-east there are several considerable bays, of which the chief are those of Alcudia and Pollensa; while on the south-west is the still more important bay of Palma. No fewer than twelve ports or harbours are enumerated round the island, of which may be mentioned Andraitx and Sóller. In the north-west Majorca is traversed by a chain of mountains running parallel with the coast, and attaining its highest elevation in Silla de Torrellas (5154 ft.). Towards the south and east the surface is comparatively level, though broken by isolated peaks of considerable height. The northern mountains afford great protection to the rest of the island from the violent gales to which it would otherwise be exposed, and render the climate remarkably mild and pleasant. The scenery of Majorca has all the picturesque quality of outline that usually belongs to a limestone formation. Some of the valleys, such as those of Valdemossa and Sóller, with their luxuriant vegetation, are delightful resorts. There are quarries of marble of various grains and colours—those near Santanyi, in the district of Manacor, being especially celebrated; while lead, iron and cinnabar have also been obtained. Coal of a jet-like character is found at Benisalem, where it was first worked in 1836; at Selva, where it has been mined since 1821; near Santa Maria and elsewhere. It is used in the industrial establishments of Palma, and in the manufacture of lime, plaster and bricks near the mines. A considerable quantity is also exported to the general trade.

The inhabitants are principally devoted to agriculture, and most of the arable land is cultivated. The mountains are terraced; and the old pine woods have in many places given way to the olive, the vine and the almond tree, to fields of wheat and flax, or to orchards of figs and oranges. For the last-mentioned fruits the valley of Sóller is one of the most important districts,
MAJORIAN—MAKART

The produce being largely transported to France. The yield of oil is very considerable, and Inca is the centre of the oil district. The wines are light but excellent, especially the Muscadel and Montona. During the summer there is often great scarcity of water; but, according to a system handed down by the Moors, the rains of autumn and winter are collected in enormous reservoirs, which contain sufficient water to last through the dry season; and on the payment of a certain rate, each landlord has his fields flooded at certain intervals. Mules are used in the agriculture and traffic of the island. The cattle are small, but the sheep are large and well fleshed. Pigs are reared for export to Barcelona, and there is abundance of poultry and small game. Brandy is made and exported in large quantities. Excellent woollen and linen cloths are woven; the silk-worm is reared and its produce manufactured; and canvas, rope and cord are largely made, from both native and foreign materials.

The roads are excellent, the four principal being those from Alcudia, Manacor, Sóller and Andraitx to the capital. Forty-eight miles of railway were open at the beginning of the 20th century. The main line runs from Palma to Manacor and Alcudia. The telegraphic system is fairly complete, and there is regular steam communication with Barcelona and Alicante. The principal towns include—besides Palma (63,937), Felanitx (11,204) and Manacor (12,408), which are described in separate articles—Andraitx (6510), Inca (7570), Llummayor (8590), Pollensa (8308), Santanyi (6692) and Sóller (8026).

MAJORIAN (Julius Valerius Majorianus), emperor of the West from 457 to 461. He had distinguished himself as a general by victories over the Franks and Alamanii, and six months after the deposition of Avitus he was declared emperor by the regent Ricimer. After repelling an attack by the Vandals on Campania (458) he prepared a large force, composed chiefly of barbarians, to invade Africa, which he previously visited in disguise. Having during his stay in Gaul defeated and concluded an alliance with Theodoric the Visigoth, at the beginning of 459 he crossed the Pyrenees for the purpose of joining the powerful fleet which he had collected at Carthagna. The Vandals king Genseric, however, after all overtures of peace had been rejected, succeeded through the treachery of certain officers in surprising the Roman fleet, most of the ships being either taken or destroyed. Majorian thereupon made peace with Genseric. But his ill-success had destroyed his military reputation; his efforts to put down abuses and improve the condition of the people had roused the hatred of the officials; and Ricimer, jealous of his fame and influence, stirred up the foreign troops against him. A mutiny broke out in Lombardy, and on the 2nd of August 461 Majorian was forced to resign. He died five days afterwards, either by dysentery or by violence. Majorian was the author of a number of remarkable laws, contained in the Theodosian Code. He remitted all arrears of taxes, the collection of which was for the future placed in the hands of the local officials. He revived the institution of defensores, defenders of cities, whose duty it was to protect the poor and inform the emperor of abuses committed in his name. The practice of pulling down the ancient monuments to be used as building material, which was connived at by venal officials, was strictly prohibited. He also passed laws against compulsory ordination and premature vows of celibacy.

See Sabinus Apollinaris, Panegyric of Majorian; Gibbon, Decline and Fall, vol. v, chap. 12; Ch. 11 of the "noves" of Majorian is given); J. B. Bury, Later Roman Empire, bk. iii.

MAJORITY (Fr. majorité; Med. Lat. majoritas; Lat. major, greater), a term signifying the greater number. In legislative and deliberative assemblies it is usual to decide questions by a majority of those present at a meeting and voting. In law, majority is the state of being of full age, which in the United Kingdom is twenty-one years of age. A person attains his majority at twelve o'clock at night of the day preceding his twenty-first birthday (see Infant; Age).

MAJUBA (properly Amajuba, Zulu for "the hill of doves"), a mountain in northern Natal, part of the Drakensberg range, rising about 7000 ft. above the sea and over 2000 ft. above the level of the surrounding country. It overlooks the Drakensberg known as Laing's Nek, is 8 m. S. of the Transvaal border and 18 m. N. of the town of Newcastle. The railway from Durban to Johannesburg skirts the base of the mountain. During the Boer War of 1880-81 Majuba was occupied on the night of the 26th of February 1881 by some 600 British troops under Sir George Pomery Colley. On the following morning the hill was stormed by the Boers under Piet Joubert and the British routed, Colley being among the slain.

MAKALA, a general designation used by the Bechuana, Matabele and kindred peoples, for conquered or slave tribes. Thus many of the tribes subjugated by the Makololo chief, Sebituane, about 1839 were called Makala (see David Livingston's Missionary Travels and Researches in South Africa, London, 1857). By early writers on southern-central Africa certain of the inhabitants of Barotseland were styled Makala; the name is more frequently used to designate the Makalanga, one of the tribes now classed as Mashonas (q.v.), who were brought into subjection by the Matabele.

MAKARAKA, or Icodo ("Cannibals"), a negroid people of Central Africa, closely related to the powerful Azande and Niam-Niam race, occupying the Bahr-el-Ghazal west of Lado. They came originally from the country of the Kibas, north of the Welle. Dr. W. Junker described them as among the most trustworthy, industrious and intelligent people of the Bahr-el-Ghazal. They are a reddish-black, with nose less flat and cheek-bones less prominent than the ordinary negroes, and, unlike the latter, do not extract the incisors. Their long silky hair is built up in the most fantastic form by means of vegetable substances. They are well known for strength and staying power.

See W. Junker, Travels in Africa (1830-1832).

MAKART, Hans (1840-1884), Austrian painter, born at Salzburg, was the son of an inspector of the imperial castle. He has been aptly called the first German painter of the 19th century. When he, as a youth, entered the Vienna Academy German art was under the rule of Cornelius's cold classicism. It was entirely intellectual and academic. Clear and precise drawing, sculptural modelling, and pictorial erudition were the qualities most esteemed; and it is not surprising that Makart, poor draughtsman to the very last, with a passionate and sensual love of colour, and ever impatient to escape the routine of art-school drawing, was found to be "devoid of all talent" and forced to leave the Vienna Academy. He went to Munich, and after two years of independent study attracted the attention of Piloty, under whose guidance he made rapid and astonishing progress. The first picture he painted under Piloty, "Lavoisier in Prison," though timid and conventional, attracted attention by its sense of colour. In the next. "The Knight, and the Water Nymphs," he first displayed the decorative qualities to which he afterwards sacrificed everything else in his work. With the "Cupid's" and "The Plague of Florence" of the next year his fame became firmly established. "Romeo and Juliet" was soon after bought by the Austrian emperor for the Vienna Museum, and Makart was invited to come to Vienna, where a large studio was placed at his disposal. In Vienna Makart became the acknowledged leader of the artistic life of the city, which in the 'seventies passed through a period of feverish activity, the chief results of which are the sumptuously decorated public buildings of the Ringstrasse.

The enthusiasm of the time, the splendour of the fêtes over which Makart presided, and the very obvious appeal of his huge compositions in their glowing richness of colour, in which he tried to emulate Rembrand's, made him appear a very giant to his contemporaries in Vienna. Yet he attracted in all Austria and Germany. The appearance of each of his ambitious historical and allegorical paintings was hailed with enthusiasm—the "Catherine Cornaro," "Diana's Hunt," "The Entry of Charles V. into Antwerp," "Abundantia," "Spring," "Summer," "The Death of Cleopatra" and the "Five Senses." He reached the zenith of his fame when, in 1879, he designed, single-handed, the costumes, scenic setting, and triumphal cars of the grand pageant with
MAKING-UP the silver wedding of

some 15,000 people participated in the pageant, all dressed in the costumes of the Rubai and Rembrandt period. Makart died in Vienna in October 1884.

Un fortunately Makart was in the habit of using such villainous pigments and mediums that in the few decades which have passed since his death, the vast majority of his large paintings have practically perished. The blues have turned into green; the bitumen has eaten through the rich brown of the colour harmonies; the thickly applied paint has cracked and in some instances crumbled away. And this loss of their chief quality has accentuated the weaknesses of these pictures—the faulty drawing, careless and hasty execution, lack of deep significance and prevalence of growing anachronisms. Important examples of his work are to be found at the galleries of Vienna, Berlin, Hamburg and Stuttgart. For the Vienna Museum he also executed a series of decorative lunettes.

MAKING-UP PRICE, a term used in the London and other British Stock Exchanges, to denote the price at which speculative bargains are carried over from one account to the next. The carrying over of a "bull" position in Eries, for example, implies a sale for cash and a simultaneous purchase for the new account, both bargains being done at the making-up price. This is fixed at noon on carry-over day, in accordance with the market price then current (see Account; Stock Exchange). The term is also used in New York, where the making-up prices are fixed at the end of a day's business, in accordance with the American system of daily settlements.

MAKO, a town of Hungary, capital of the county of Csanád, 135 m. S.E. of Budapest by rail. Pop. (1900), 33,701. It is situated near the right bank of the Maros, and is a typical Hungarian town of the Alföld. The most noteworthy building is the palace of the bishop of Csanád, whose usual residence is in Temesvár. The town possesses numerous mills, and the surrounding country is fertile. The communal lands are extensive; they afford excellent pasturage for horses and sheep and also for large herds of horned cattle, for the size and quality of which Makó has obtained a high reputation.

MAKRAN, or MAKRAN, a province of Baluchistan, forming the Arabian Sea from Persia almost to Sind for about 200 m. It is subject to the khan of Kalat under British political supervision. Estimated area, 26,000 sq. m.; estimated pop. (1903), 78,000. The long lateral valley of Koj is usually associated with Makran in early geographical records. The Koj-Macoran of Marco Polo is the Makran of to-day.

The long stretch of sandy foreshore is broken on the coastline by the magnificent cliffs of Malan, the hammer-shaped headlands of Ormara and Gwadar, and the precipitous cliffs of Jebel Zarain, near Pasni. Within them lies the usual frontier band of parallel ridges, alternating with narrow valleys. Amongst them the ranges called Talana and Talur are conspicuous by their height and regular configuration. The normal conformation of the Baluchistan frontier is somewhat emphasized in Makran. Here the volcanic action, which preceded the general upheaval of recent strata and the folding of the edges of the interior highlands, is still in evidence in occasional boiling mud volcanoes or mud volcanoes. At the burning summit of the Kuh-i-taftan (the burning mountain of the Persian frontier) which is the highest active volcano in Asia (13,000 ft.), and probably the farthest inland. Evidence of extinct mud volcanoes exists through a very wide area in Baluchistan and Seistan. Probably the miri, or fort, at Quetta represents one of them. The coast is indented by several harbours. Ormara, Khor Kalmar, Pasni and Gwadar are all somewhat difficult of approach by reason of a sand-bar which appears to extend along the whole coastline, and which is very possibly the last evidence of a submerged ridge; and they all are subject to a very lively surf under certain conditions of wind. Of these the port of Gwadar (which belongs to Muscat and is therefore foreign territory) is the most important. They all are (or were) stations of the Indo-Persian telegraph system which unites Karachi with Bushire. With the exception of the Kej valley, and that of the Bolinda, which is an affluent of the Kej, there are no considerable spaces of cultivation in Makran. These two valleys seem to concentrate the whole agricultural wealth of the country. They are picturesque, with thick groves of date palms at intervals, and are filled with crops and orchards. They are indeed exceedingly beautiful; and yet the surrounding waste of hills is chiefly a barren repetition of sun-cracked crags and ridges with parched and withered valleys intersecting them, where a trickle of salt water leaves a white and leprous streak amongst the faded tamarisk or the yellow stalks of last season's grass. Makran is the home of remnants of an innumerable company of mic.ed people gathered from the four corners of Asia and eastern Africa. The ancient Dravidians, of whom the Brahm is typical, still exist in many of the districts which are assigned to them in Herodotus. Amongst them there is always a prominent Arab element, for the Arabs held Makran even before they conquered Sind and made the Kej valley their trade highway to India. There are negroes on the coast, bred from imported slaves. The Meds of the Indus valley still form the greater part of the fishing population, representing the Ichtchophagi of Arrian. The old Tajik element of Persia is not so evident in Makran as it is farther north; and the Karak pirates whose depredations led to the invasion of India and the conquest of Sind, seem to have disappeared altogether.

The fourth section includes the valleys formed by the Rakshan and Mashkel, which, sweeping downwards from the Kalat highlands and the Persian border east and west, unite to break through the intervening chain of hills northward to form the Mashkel swamps, and define the northern limits of Makran. In these valleys are narrow strips of very advanced cultivation, the dates of Panjgur being generally reckoned superior even to those of the Euphrates. The great Mashkel swamp and the Kharan desert to the east of it, mark the flat phase of southern Baluchistan topography. It is geologically part of an ancient inland lake or sea which included the present swamp regions of the Helmund, but not the central depression of the Lora. The latter is buttressed against hills at a much higher elevation than the Kharan desert, which is separated from the great expanse of the Helmund desert within the borders of Afghanistan by a transverse band of serrated hills forming a distinct watershed from Nushki to Seistan. Here and there these jagged peaks appear as if half overwhelmed by an advancing sea of sand. They are treeless and barren, and water is but rarely found at the edges of their foot-hills. The Koh-i-Sultan, at the western extremity of the northern group of these irregular hills, is over 6,000 ft. above sea-level, but the general level of the surrounding deserts is only about 2000 ft., sinking to 1500 ft. in the Mashkel Hamun and the Gaol-i-Zirreh.

The whole of this country has been surveyed by Indian surveyors and the boundary between Persia and British Baluchistan was demarcated by a commission in 1895-1896. In 1898 a column of British troops under Colonel Mayne was despatched to Makran by sea, owing to a rebellion against the authority of the khan of Kalat, and an attack made by some Makran chiefs on a British survey party. The campaign was short and terminated with the capture of the Kej citadel. Another similar expedition was required in 1901 to storm the fort at Nodiz. The headquarters of the native governor, under the Khan of Kalat, are at Turbat, with deputies at Tump, Kolwa, Pasni and Panjgur. A levy corps, with two British officers, is stationed along the eastern frontier. The port of Gwadar forms an enclave belonging to the sultan of Muscat.

T. H. H."

MAKSSORA, the term in Mahommadian architecture given to the sanctuary or praying-chamber in a mosque, which was sometimes enclosed with a screen of lattice-work; the word is occasionally used for a similar enclosure round a tomb.

MALABAR, a district of British India, in the Madras Presidency. Geographically the name is sometimes extended to the entire western coast of the peninsula. Properly it should apply to the strip below the Ghats, which is inhabited by people speaking the Malayalam language, a branch of the Dravidian stock, who form a peculiar race, with castes, customs and traditions of their own. It would thus be coextensive with the old kingdom of Chera, including the modern states of
Travancore and Cochim, and part of Kanara. In 1901 the total number of persons speaking Malayalam in all India was 6,020,304.

The district of Malabar extends for 145 m. along the coast, running inland to the Ghats with a breadth varying from 70 to 25 m. The administrative headquarters are at Calicut. Area, 5709 sq. m. Malabar is singularly diversified in its configuration; from the eastward, the great range of the Western Ghats, only interrupted by the Palghat gap, looks down on a country broken by long spurs, extensive ravines, dense forests and tangled jungle. To the westward, gentler slopes and downswells, and gradually widening valleys closely cultivated, succeed the forest uplands, till, nearer the seaboard, the low laterite table-lands shelve into rice plains and backwaters fringed with coconut palms. The coast runs in a south-easterly direction, and forms a few headlands and small bays, with a natural harbour in the south at Cochin. In the south there is considerable extent of table-land. The mountains of the Western Ghats run almost parallel to the coast, and vary from 3000 to 7000 ft. in height. One of the most characteristic features of Malabar is an all but continuous chain of lagoons or backwaters lying parallel to the coast, which have been formed by the action of the waves and shore currents in obstructing the waters of the rivers. Connected by artificial canals, they form a cheap means of transit; and a large local trade is carried on by inland navigation. Fishing and fish curing is an important industry. The forests are extensive and of great value, but they are almost entirely private property. The few tracts which are conserved have come into government hands by escheat or by contract. Wild animals include the elephant, tiger, panther, bison, sambar, spotted deer, Nilgiri ibex, and bear. The population in 1901 was 2,800,555, showing an increase of 5.6% in the decade.

The staple crop is rice, the next most important product being cocoa-nuts. Coffee is grown chiefly in the upland tract known as the Wynaad, where there are also a few acres under tea. The Madras railway crosses the district and has been extended from Calicut to Cannanore along the coast. There are eleven seaports, of which the principal are Calicut, Tellecherry, Cannanore and Cochin. The principal exports are coffee, cocoa-nut products and timber. There are factories for cleaning coffee, pressing coir and making matting, making tiles, sawing timber and weaving cotton.

See Malabar District Gazetteer (Madras, 1908).

MALABARI, BEHRAMJI (1853–), Indian journalist and social reformer, was born in 1853 at Baroda, the son of a poor Parsi in the employment of the state, who died shortly after his birth. His mother took him to Surat, where he was educated in a mission school, but he never succeeded in gaining an academical degree. Coming to Bombay, he fell under the influence of Dr John Wilson, principal of the Scottish College. As early as 1875 he published a volume of poems in Gujarati, followed in 1877 by The Indian Muse in English Garb, which attracted attention in England, notably from Tennyson, Max Muller, and Florence Nightingale. His life work began in 1880 when he acquired the Indian Spectator, which he edited for twenty years until it was merged in the Voice of India. In 1901 he became editor of East and West. Always holding aloof from politics, he was an ardent and indefatigable advocate of social reform in India, especially as regards child marriage and the remarriage of widows. It was largely by his efforts, both in the press and in tours through the country, that the Age of Natives was compassed in 1891. His account of his visits to England, entitled The Indian Eye on English Life (1893), passed through three editions, and an earlier book of a somewhat satirical nature, Gujarat and the Gujaratis (1883), was equally popular.

See R. P. Karkaria, India, Forty Years of Progress and Reform, (London, 1896).

MALABON, a town of the province of Rizal, Luzon, Philippine Islands, 1 m. inland from the shore of Manila Bay and 3 m. N. of the city of Manila, with which it is connected by an electric tramway. Pop. (1903), 20,136. The leading industries are the refining of sugar, fishing, trade, the weaving of jussi cloth, the making of cigars, and the cultivation of ilang-ilang-trees (Cananga odorata) for their flowers, from which a fine perfume is distilled; ilang-ilang is one of the principal exports, mostly to France. Tagalog and Spanish are the principal languages. Malabon was formerly known as Tambobong.

MALACCA, a town on the west coast of the Malay Peninsula, in 2° 14′ N., 102° 12′ E., which, with the territory lying immediately around and behind it forms one of the Straits Settlements, and gives its name to the Straits which divide Sumatra from the Malay Peninsula. Its name, which is more correctly transliterated melética, is that of a species of jungle fruit, and is also borne by the small river on the right bank of which the old Dutch town stands. The Dutch town is connected by a bridge with the business quarter on the left bank, which is inhabited almost exclusively by Chinese, Eurasians and Malays.

Malacca, now a somnolent little town, a favourite resort of rich Chinese who have retired from business, is visited by few ships and is the least important of the three British settlements on the Straits which give their name to the colony. It has, however, a remarkable history. The precise date of its foundation cannot be ascertained, but there is strong reason to believe that this event took place at the earliest in the 14th century. The Roman youth Ludovico Bartheza is believed to have been the first European to visit it, some time before 1503; and in 1509 Diogo Lopez de Siqueira sailed from Portugal for the express purpose of exploiting Malacca. At first he was hospitably received, but disagreements with the natives ensued and word was brought to Siqueira by Magellan, who was one of his company, that a treacherous attack was about to be made upon his ships. Siqueira then sent a native man and woman ashore "with an arrow passed through their skulls" to the sultan, "who was thus informed," says de Barros, "through his subjects that unless he kept a good watch the treachery which he had perpetrated would be punished with fire and sword." The sultan retaliated by arresting Ruy de Araujo, the factor, and twenty other men who were ashore with him collecting cargo for the ships. Siqueira immediately burned one of his vessels and sailed direct for Portugal. In 1510 Mendez de Vasconcellos with a fleet of four ships set out from Portugal "to go and conquer Malacca," but d'Alboquerque detailed him to Goa, and it was not until 1511 that d'Alboquerque himself found time to visit Malacca and seek to rescue the Portuguese prisoners who all this time had remained in the hands of the sultan. An attack was delivered by d'Alboquerque on the 25th of July 1511, but it was only partially successful, and it was not until the 4th of August, when the assault was repeated, that the place finally fell. Since that time Malacca has continued to be the possession of one or another of the European Powers.

It was a Portuguese possession for 130 years, and was the headquarters of their trade and the base of their commercial explorations in south-eastern Asia while they enjoyed, and later while they sought to hold, their monopoly in the East. It was from Malacca, immediately after its conquest, that d'Alboquerque sent d'Abreu on his voyage of discovery to the Moluccas, or Spice Islands, which later were the objective of Magellan's voyage of circumnavigation. During the Portuguese tenure of Malacca the place was attacked at least twice by the Achiene; its shipping was harried by Lancetor in 1592, when the first British fleet made its way into these seas; it was besieged by the Dutch in 1606, and finally fell to a joint attack of the Dutch and British, after a long siege, to the great delight of the Portuguese government that St Francis Xavier started a mission in Malacca, the first Christian mission in Malayan lands.

The Dutch held Malacca till 1795, when it was taken from them by Great Britain, and the Dutch system of monopoly in the straits was fortieth abolished. The colony was restored to the Dutch, however, in 1818, but six years later it came finally into the hands of Great Britain, being exchanged by a treaty with Holland for the East India Company's settlement of Benkulen and a few other unimportant places on the western
coast of Sumatra. By this treaty the Dutch were precluded from interference in the affairs of the Malay Peninsula, and Great Britain, from similar action in regard to the States of Sumatra, with the sole exception of Achin, the right to protect that state being maintained by Great Britain until 1872 when it was finally abandoned by a treaty concluded with Holland in that year. The Dutch took advantage of this immediately to invade Achin, and the strife begun in 1873 still continues and is now a mere war of extermination. It was not until 1833 that the whole territory lying at the back of Malacca was finally brought under British control, and as late as 1887 the Negri Sembilan, or Nine States, which adjoin Malacca territory on the east and north-east, were completely independent. They to-day form part of the Federated Malay States, which are under the protection of Great Britain, and are governed with the assistance and by the advice of British officers.

Malacca, in common with the rest of the Straits Settlements, was administered by the government of India until 1867, when it became a crown colony under the control of the Colonial Office. It is to-day administered by a resident council, who is responsible to the governor of the Straits Settlements, and by a number of district officers and other officials under his direction. The population of the town and territory of Malacca was 92,170 in 1887; 118,000 in 1897; 24,482,679 in 1906. There is a good bond station at Malacca and a comfortable seaside bungalow at Tanjong Kling, seven miles from the town. Malacca is 118 m. by sea from Singapore and 50 m. by rail from Seremban, the capital of the Negri Sembilan. There is excellent snap-shooting to be had in the vicinity of Malacca.

C.).

MALACHI, the name assigned to the last book of the Old Testament in English (the last of the “prophets” in the Hebrew Bible), which according to the title (Mal. i. 1) contains the “word of Yahweh to Israel by the hand of Malachi.” In form the word means “my messenger.” It could be explained as a contraction of Malachih, “messenger of Yahweh”; but the Septuagint is probably right in not regarding it as a proper name (“by the hand of His messenger”). Not only do we know nothing from internal or external evidence of the existence of a prophet of this name,1 but the occurrence of the word in the title is naturally explained as derived from iii. 1: “Behold, I send my messenger” (cf. ii. 7). The prophecy must, therefore, be regarded as anonymous; the title was added by the compiler who wrote similar editorial titles to the anonymous prophecies beginning Zech. ix. 1, xii. 1.

The closing prophecy may possibly be a later addition (90 Marti) rounding off the prophetic canon by reference to the two great names of Moses and Elijah, and their characteristic activities. In this case, “Elijah” will represent an early interpretation (cf. Ecclus. xlvii. 10) of the “messenger,” originally conceived as a purely ideal figure. The only other passage in the book whose originality is not generally accepted is that referring to mixed marriages (ii. 11, 12).

It is the Deuteronomic law that is most familiar to him, as applied by him to his own and to his hearers. He is at home in the law, and the Deuteronomic phrase “statutes and judgments” (iv. 4), from his language as to tithes and offerings (iii. 8, 10; cf. Deut. xii. 11; xxvi. 12), and especially from his conception of the priesthood as resting on covenant (i. 10), make it seem reasonable to regard the term “whole tithe”—the Deuteronomic phrase for the tithes in which the Levites shared—in each township, but brought into the treasury at the Temple. But this was a modification of the Deuteronomic law naturally called for under the circumstances of the return from Babylon, and Neh. x. and xii. produce the impression that it was not introduced for the first time by Ezra and Nehemiah, though the collection of the tithes was enforced by them. See further, W. R. S. in O. T. J. C. ii. 425–427.

2 Torrey (Ency. Bib. c. 2908) holds that the reference here is purely figurative; “Jehovah has dealt falsely with the wife of his youth, the covenant religion, and is wedding a strange cult.” But he assigns the book to the 4th cent.

3 This closing prophecy may possibly be a later addition (90 Marti) rounding off the prophetic canon by reference to the two great names of Moses and Elijah, and their characteristic activities. In this case, “Elijah” will represent an early interpretation (cf. Ecclus. xlvii. 10) of the “messenger,” originally conceived as a purely ideal figure. The only other passage in the book whose originality is not generally accepted is that referring to mixed marriages (ii. 11, 12).

It is the Deuteronomic law that is most familiar to him, as applied by him to his own and to his hearers. He is at home in the law, and the Deuteronomic phrase “statutes and judgments” (iv. 4), from his language as to tithes and offerings (iii. 8, 10; cf. Deut. xii. 11; xxvi. 12), and especially from his conception of the priesthood as resting on covenant (i. 10), make it seem reasonable to regard the term “whole tithe”—the Deuteronomic phrase for the tithes in which the Levites shared—in each township, but brought into the treasury at the Temple. But this was a modification of the Deuteronomic law naturally called for under the circumstances of the return from Babylon, and Neh. x. and xii. produce the impression that it was not introduced for the first time by Ezra and Nehemiah, though the collection of the tithes was enforced by them. See further, W. R. S. in O. T. J. C. ii. 425–427.

his time was the outcome of a lowered morality, not of a clearer spiritual vision.” A strong sense of the unique privileges of the children of Jacob, the objects of electing love (i. 2), the children of the Divine Father (ii. 10), is combined with an equally strong assurance of Yahweh’s righteousness notwithstanding the many miseries that pressed on the unhappy inhabitants of Judaea. At an earlier date the prophet Haggai had taught that the people could not expect Yahweh’s blessing while the Temple lay in ruins. In Malachi’s time the Temple was built (i. 10) and the priests waited in their office, but still a curse seemed to rest on the nation’s labors (iii. 9). To Malachi the reason of this is plain. The “law of Moses” was forgotten (iv. 4 (iii. 22)); let the people return to Yahweh, and He will return to them. It was in vain to complain, saying, “Every one that doeth evil is good in the eyes of Yahweh,” or “Wherein shall we return?” Obedience to the law is the sure path to blessing (ii. 17-iii. 12).

He calls the people to repentance, and he enforces the call by proclaiming the approach of Yahweh in judgment against the sorcerers, the adulterers, the false swears, the oppressors of the poor, the orphan and the stranger. Then it shall be seen that He is indeed a God of righteous judgment, distinguishing between those who serve Him and those that serve Him not. The Sun of Righteousness shall shine forth on those that fear Yahweh’s name; they shall go forth with joy, and tread the wicked under foot. The conception of the day of final decision, when Yahweh shall come suddenly to His temple (iii. 1) and confound those who think the presumptuous godless happy (iii. 15), is taken from earlier prophets, but is applied wholly within the Jewish nation. The day of Yahweh would be a curse, not a blessing, if it found the nation in its present state: the priests listlessly performing a fraudulent service (ii. 8-9), the people bound by marriage to heathen women, while the tears of the daughters of Israel, thrust aside to make way for strangers, cover the altar (ii. 11-16), all faith in divine justice gone (ii. 17; iii. 14 seq.), sorcery, uncleanness, falsehood and oppression rampant (iii. 5), the house of God deprived of its dues (iii. 8), and the true fearers of God a little flock gathered together in private exercises of religion (perhaps the germ of the later synagogue) in the midst of a godless nation (iii. 16). That the day of Yahweh is delayed in such a state of things is but a new proof of His unchanging love (iii. 6), which refuses to consume the sons of Jacob. Meantime He is about to send His messenger to prepare His way before Him. The prophet Elijah must reappear to bring back the hearts of fathers and children before the great and terrible day of Yahweh come. Elijah was the advocate of national decision in the great concerns of Israel’s religion; and it is such decision, a clear recognition of what the service of Yahweh means, a purging of His professed worshipers from hypocritical and half-hearted service (iii. 3) that Malachi with his intense religious earnestness sees to be the only salvation of the nation. In thus looking to the return of the ancient prophet to do the work for which later prophecy is too weak, Malachi unconsciously signals the decay of the order of which he was one of the last representatives; and the somewhat mechanical measure which he applies to the people’s sins, as for example when he teaches that if the sacred dues were rightly paid prosperous seasons would at once return (iii. 10), heralds the advent of that system of formal legislation which thought that all religious duty could be reduced to a system of set rules. Yet Malachi himself is no mere formalist. To him, as to the Deuteronomic legislation, the forms of legal observance are of value only as the fitting expression of Israel’s peculiar sonship and service, and he shows himself a true prophet when he contrasts the worthless ministry of unwilling priests with the pure offering of prayer and praise that rises from the implicit monotheism of even Gentile worship (i. 11), or when he asserts the brotherhood of all Israelites under their one Father (ii. 10), not merely as a ground of separation from the heathen, but as inconsistent with the selfish and cruel freedom of divorce current in his time. The book is a significant landmark in the religious history of Israel. Its emphasis on the observance of ritual finds fullest development in the Priestly Code, subsequently promulgated; its protest against foreign marriages is made effective through the reforms of Ezra and Nehemiah; the influence of its closing words on later expectation is familiar to every reader of the new Testament.

The style of Malachi, like his argument, corresponds in its generally prosaic character to that transformation or decay of prophecy which began with Ezekiel; and Ewald rightly called attention to the fact that the conduct of the argument already shows traces of the dialectical manner of the schools. Yet there is a simple dignity in the manner not unworthy of a prophet, and rising from time to time to poetical rhythm.

Malachi in Hastings’ Dict. of the Bible, ii. 218-222 (1900); C. C. Torrey, id. in Ency. Bibl. iii. c. 2907-2910 (1902); Marti, Dodekopropheton (1904); Stade, Biblische Theologie der Alten Test. (1905); Driver, The Minor Prophets, ii. (Century Bible, 1906).

MALACHITE, a copper-ore of fine green colour, sometimes polished as an ornamental stone. The name is derived from Gr. μαλαχίς, the mallow, in allusion to the colour of the mineral being rather like that of the mallow-leaf. Malachite was perhaps one of the green minerals described by Theophrastus under the general name of σμαραγδος; and according to the late Rev. C. W. King it was probably the smaragdus medicus of Pliny, whilst his molochites seems to have been a different stone from our malachite and may have been a green Jasper. It is suggested by J. L. Myres (Ency. Bibl.) that malachite may have been the Heb. sokham, of the high priest’s breastplate.

Malachite is a basic cupric carbonate, represented by the formula CuO·CuCO₃, and has usually been formed by the action of meteoric agencies on other copper-minerals; hence it is found in the upper part of ore-deposits, often as an incrustation, and occasionally as a pseudomorph after cuprite, chalcocite, &c. When formed, as commonly happens, by the alteration of copper-pyrites the iron of this mineral usually takes the form of limonite, which may remain associated with the malachite. Occasionally, though but rarely, malachite occurs in small dark green prismatic crystals of the monoclinic system. Its usual mode of occurrence is in nodular or stalagmitic forms, with a mammillated, reniform or botryoidal surface, whilst in other cases it forms fibrous, compact or even earthy masses. The nodules, though commonly dull on the outside, may display on fracture a beautiful zonary structure, the successive layers often succeeding each other as curved deposits of light and dark tints. The colours include various shades of apple-green, grass-green, emerald-green and verdigris-green. Certain varieties exhibit a finely fibrous structure, producing on the fractured surface a soft silken sheen.

Malachite is found in greater or less quantity in most copper-mines, the finer varieties useful for ornamental purposes are of very limited occurrence, and the lapidary has generally drawn his supply from Russia and Australia. The principal source in recent years has been the Medno-Rudiansk mine near Nizhne Tagilsk, on the Siberian side of the Urals, but it was formerly obtained from mines near Bogoslav to the north and Guminshov to the south of this locality. A mass from Guminshov, preserved in the museum of the Mining Institute of St Petersburg weighs 3240 lb, and still larger masses have been found near Nizhne Tagilsk. The mineral is prized in

1 Welch in D.B. iii. 220.
2 Matt. xviii. 3, 4; 10-13; xxvii. 47, 49; John i. 21, 25.
Russia for use in mosaic work, and for the manufacture of vases, snuff-boxes and various ornamental objects. Even folding doors, snuff-boxes, table- tops and other articles of furniture have been executed in malachite, the objects being veneered with thin slabs cleverly fitted together so as to preserve the pattern, and having the interspaces filled up with fragments and powder of malachite applied with a cement. The malachite is sawn into slabs, ground with emery and polished with tripoli. Its hardness is less than 4, but it takes a good polish like marble: it is rather denser than marble, having a specific gravity of 3.7 to 4, but it is more difficult to work, in consequence of a tendency to break along the curved planes of deposition. Exceptionally fine examples of the application of malachite are seen in some of the columns of St Isaac's Cathedral in St Petersburg, which are hollow iron columns encrusted with malachite. Large masses of ornamental malachite have been found in Australia, especially at the old Burra Burra coppermine in South Australia. The Copper Queen and her mines in Arizona have yielded fine specimens of malachite associated with azurite, and polished slabs of the mixed minerals sometimes show the vivid green and the deep blue carbonate in very striking contrast. This natural association, cut as an ornamental stone, has been named, by Dr G. F. Kunz, azurmalachite. Malachite is occasionally used for cameo-work, and some fine antique examples are known. It was formerly worn as an amulet to preserve the wearer from lightning, contagion and witchcraft.

The mineral, when ground, has been used as a pigment under the name of "mountain green." The coarser masses are extensively used, with other minerals, for paints. Malachite about 57% of metal. "Blue malachite" is a name sometimes given to azurite (q.v.), whilst "siliceous malachite" is a term inappropriately applied to chrysocolla (q.v.).

MALACHOWSKI, STANISLAW (1735-1809), Polish statesman, the younger son of Stanislaw Malachowski, palatine of Posen, the companion in arms of Sobieski. From his youth Malachowski laboured zealously for the good of his country, and as president of the royal courts of justice won the honourable title of the "Aristides." He was first elected a deputy to the Coronation Diet of 1764, and the great Four Years' Diet unanimously elected him its speaker at the beginning of its session in 1788. Accurately gauging the situation, Malachowski speedily gathered round him all those who were striving to uphold the falling republic and warmly supported every promising project of reform. He was one of the framers of the constitution of the 3rd of May 1791, exceeding in liberality all his colleagues and advocating the extension of the franchise to the towns and the emancipation of the serfs. He was the first to enter his name as a citizen of Warsaw in the civic register and to open negotiations with his own peasantry for their complete liberation. Disappointed in his hopes by the overthrow of the constitution, he resigned office and left the country in 1792, going first to Italy and subsequently to his estates in Galicia, where he was imprisoned for a time on a false suspicion of conspiracy. In 1807 Malachowski was placed at the head of the executive committee appointed at Warsaw after its evacuation by the Prussians, and when the grand duchy of Warsaw was created Malachowski became president of the senate under King Frederick Augustus of Saxony. In the negotiations with the Austrian government concerning the Galician salt-mines Malachowski came to the assistance of the deposed treasury by hypothecating all his estates as an additional guarantee. In 1809 he died at Warsaw. His death was regarded as a public calamity, and multitudes followed his remains to their last resting-place in the Church of the Holy Cross. In all the other towns of the grand duchy funeral services were held simultaneously as a tribute of the respect and gratitude of the Polish nation.

See August Sokoowski, Illustrated History of Poland (Pol.), vol. iv. (Vienna, 1900); Life and Memoirs of S. Malachowsky, edited by Lucian Siemieniak (Pol; Cracow, 1853). (R. N. B.)

MALACHY, ST (c. 1094-1148), otherwise known as Malo-Maodhog (or Maelmaodhog) or Us Mairg, archbishop of Armagh and papal legate in Ireland, was born at Armagh. His father, an Irish clergyman, the Fearleighinn, or lector, at the university, was said to have been of noble family. Having been ordained to the priesthood, he for some time acted as vicar of Archbishop Cellus or Ceallach of Armagh, and carried out many reforms tending to increase conformity with the usage of the Church of Rome. In order to improve his knowledge of the Roman ritual he spent four years with Malchus, bishop of Lismore (in Munster), a strong advocate of Romanism. Here he became acquainted with Cormac MacCarth, king of Desmond, who had sought refuge with Malchus, and, when he subsequently regained his kingdom, rendered great services to Malachy. On his return from Lismore, Malachy undertook the government of the decayed monastery of Bangor (in Co. Down), but very soon afterwards he was elected bishop of Connor (now a small village near Ballymena). After the sack of that place by the king of Ulster he withdrew into Munster; here he was kindly received by Cormac MacCarth, who built for him a monastery at the town of Ibrach (in Kerry). Meanwhile he had been designated by Celsus (in whose family the see of Armagh had been hereditary for many years) to succeed him in the archbishopric; in the interests of reform he reluctantly accepted the dignity, and thus became involved for some years in a struggle with the so-called heirs. Having finally settled the diocese, he was permitted, as had been previously stipulated by himself, to return to his former diocese, or rather to the smaller and poorer portion of it, the bishopric of Down. Although the Roman party had by this time obtained a firm hold in the north of Ireland, the organization of the Church had not yet received the sanction of the pope. Accordingly, in 1139, Malachy set out from Ireland with the purpose of soliciting from the pope the pallium (the token of archiepiscopal subjection to Rome) for the archbishop of Armagh. On his way to Rome he visited Clairvaux, and thus began his lifelong friendship with St Bernard. Malachy was received by Innocent II. with great honour, and made papal legate in Ireland, though the pope refused to grant the pallium until it had been unanimously applied for "by a general council of the bishops, clergy and nobles." On his way home Malachy revisited Clairvaux, and took with him from there four members of the Cistercian order, by whom the abbey of Mellifont (in the county of Louth) was afterwards founded in 1141. For the next eight years after his return from Rome Malachy was active in the discharge of his legatine duties, and in 1148, at a synod of bishops and clergy held in Inis-Patrick (St Patrick's Island, near Skerries, Co. Dublin), he was commissioned to return to Rome and make fresh application for the pallium; he did not, however, get beyond Clairvaux, where he died in the arms of St Bernard on the 2nd of November 1148. The object of his life was realized four years afterwards, in 1152, during the legateship of his successor, Malachy was canonized by Clement III. in 1190.

The influence of Malachy in Irish ecclesiastical affairs has been compared with that of Boniface in Germany. He reformed and reorganized the Irish Church and brought it into subjection to Rome; like Boniface, he was a zealous reformer and a promoter of monasticism. But perhaps his chief claim to distinction is that of having opened the first Cistercian monastery in Ireland, five more being soon afterwards established. Several works are attributed to him, but are all probably spurious. The most curious of these is a Prophecy concerning the Future Roman Pontiffs, which has produced an extensive literature. It is now generally attributed to the year 1950, and is supposed to have been forged to support the election of Cardinal Simoncelli to the papal chair.

St Bernard's Life of Malachy, and two sermons on his death, will be found in J. P. Migne, Patrologia Latina, clxxxii., clxxxiii.; also Annals of the Kingdom of Ireland by the Four Masters, ed. J. O'Donovan (Dublin, 1851); G. Germaino, Vita, gesti e pridttio dei padri san Malachia (Naples, 1670); the ecclesiastical histories of Ireland by J. Lanigan (see and W. D. Kelle, ed. (1875); A. Bellesheim, Geschichte der katholischen Kirche in Irland, Bd. I. (Mainz, 1895); G. T. Stokes, Ireland and the Celtic Church (6th ed., 1907); J. O'Hanlon, Life of Saint Malachi (Dublin, 1859); articles in Dictionary of National Biography and Herbart-Hauers Realencyklopädie für protestantische Theologie. On the Prophecy, see the

MALACHOWSKI—MALACHY, ST
MALACOSTRACA. Under this zoological title are included several groups of Crustacea (q.v.), united by characters which attest their common origin, though some, and probably all of them, were already separated in distant geological ages, and some have now attained a peculiar isolation. Throughout the whole, the researches made since 1860 have not only added a great throng of new species, genera and families, but have thrown a flood of light upon questions of their phylogeny, systematic arrangement, horizontal and bathymetric distribution, organization, habits of life and economic importance. There are at least seven orders: the stalk-eyed Brachyura, Macrura, Schizopoda, Stomatopoda, and the sensile-eyed Symphoda, Isopoda, Amphipoda. An ocular segment claimed by the former division is not present or in no case demonstrable in the latter. In neither group there is a terminal segment or telson, neither larger nor more obsolescent, whether articulated or unossified, carry appendages, unless occasionally in fusion with itself. Between the eyes and the tail-piece in all the orders nineteen segments are counted, the proof of a segment's existence depending on its separateness, complete or partial, or on a sutural indication, or else on the pair of appendages known to belong to it. All these marks may fail, and then the species must be proved to be Malacostracan by other evidence than the number of its segments; but if some exceptions exhibit fewer, none of the Malacostraca exhibits more than 19 (+1 or +2) segments, unless the Nebaliidea be included. Of the corresponding pairs of appendages thirteen belong to the head and trunk, two pairs of antennae, one pair of mandibles, two pairs of maxillae, followed by three which may be all maxillipeds or may help to swell the number of trunk-legs to which the next five pairs belong. The abdomen or pleon carries the remaining six pairs of which the first three are pereiopods, the remaining uropods. Underlying the diversity of names and functions and countless varieties of shape, there is a common standard to which the appendages in general can be referred. In the maxillipeds and the trunk-legs it is common to find or otherwise easy to trace a seven-jointed stem, the endopod, from which may spring two branches, the epiopod from the first joint, the exopod from the second. The first antennae are exceptional in branching, if at all, at the third joint. In the mandibles and maxillae some of the terminal joints of the stem are invariably wanting. In the rest of the appendages they may either be wanting or indistinguishable. The latter obscurity results either from coalescence, to which all joints and segments are liable, or from subdivision, which occasionally affects joints even in the trunk-legs. The carapace, formerly referred only to the antennar-mandibular segments, may perhaps in fact contain elements from any number of other segments of head and trunk, Huxley, Alcock, Bouvier giving support to this opinion by the sutureal or other divisional lines in Potamonus, Nephrops, Thalassina, and various fossil genera. Not all questions of classification internal to this division are yet finally settled. Between the Brachyura and Macrura some authors uphold an order Anomura, though in a much restricted sense, the labours of Huxley, Boas, Alcock and conjointly Alphonse Milne-Edwards and Bouvier, having resulted in restoring the Dromiidea and Raninidae to the Brachyura, among which de Haan long ago placed them. The French authors argue that from the macuran lobsters (Nephropsidae) anciently diverged two lines: one leading through the Dromiida to the genuine Brachyura; or crabs, the other independently to the Anomura proper, which may conveniently be named and classed as Anomura anomala. Spence Bate maintained that the Schizopoda ought not to form a separate order, but to be ranged them, and this group among the other appendages of the Palaemonidae than to those of any other group” (“Challenger Reports,” “Macrura,” p. 472, 1888). According to Sars, the

1 In Huxley's terminology the first two or three of the joints of the stem constitute the "endopodite," from which spring the "endopodite" and "exopodite."
shells as houses or fortresses, ready built and light enough for easy transport, is obviously discounted by a twofold inconvenience. There is nothing to ensure that the supply will be equal to the demand, and Nature has not arranged that the borrowed tenement shall continue to grow with the growth of its new tenant. To meet these defects it is found that numerous species encourage or demand the companionship of various zoophytes, simple or colonial. These sometimes completely absorb the shell on which they are settled, and then act as a substitute for it, and in any case by their outgrowth they extend the limits of the dwelling, so that the inmate can grow in comfort without having to hunt or fight for a larger abode. Among the Lophidae, or stone crabs, besides important readjustments of classification (Bouvier, 1895, 1896), should be dealing with the order at large; "British Schizopoda," by Norman Ann. Nat. Hist. (1892); "Decapoden und Schizopoden" (Plankton-Expedition, 1893); "Euphausiiden," by Stebbing, Proc. Zool. Soc. (London, 1900); Myisidae of the Russian Empire, by Zerniavski (1882-1898); and Myisidae of the Caspian, by Sars (1893-1895-1897).

4. STOMATOPoda.—This order, at one time a medley of heterogeneous forms, is now confined to the singularly compact group of the Stomatopoda. Five families are recognized, and they are usually distinct, and here two characters quite foreign to all the preceding groups come into view. The second maxillipeds are developed into powerful prehensile organs, and the branchiae, instead of being connected with the appendages of head and trunk, are developed on the pleopods, appendages of the abdomen. At least three segments of the trunk are left uncovered by the carapace. The developing eggs are not carried about by the mother, but deposited in her subcutaneous burrow, 'where they are aerated by the currents of water produced by the abdominal feet of the parent.' An excellent synopsis of the genera and species is provided by R. P. Bigelow (Proc. U.S. Mus. vol. xvii, 1894). For the habits and peculiarities of these and many other Crustaceans, A. E. Verrill and S. I. Smith on the Invertebrates of Vineyard Sound should be consulted (1874). The general subject has been illuminated by the labours of Claus, Miers, Brooks ("Challenger" Report, 1886), and the latest word on the relationship between the various larvae and their respective genera has been spoken by H. J. Hansen (Plankton-Expedition Report, 1895). The striking forms of Alima and Erichthus, at one time regarded as distinct genera, are now with more or less certainty affiliated to their several allied parents.

5. SYMPODA.—This order of sessile-eyed decapods is absolutely unknown to science till 1779. A species certainly belonging to it was described by Lepkephin in 1780, but the obscure Gammarus eosa, 'food Gammarus' beloved of herrings, described by J. C. Fabricius in 1793, may also be one of these enigmatic possibilities are implied in Diastylis rathkii, Kröyer, one of the largest forms, which, though slender and rarely an inch long, in its favourite Arctic waters is found in incalculable masses, in thousands of specimens (Stuxberg, 1880). Far on in the 19th century

**Fig. 1.** Neolithodes grimaldii, A. Milne-Edwards and Bouvier, noticed the evidence of their cosmopolitan range, and the species Neolithodes ayassii (Smith) and N. grimaldii, Milne-Edwards and Bouvier, which carry to an extreme the spinosity characteristic of the group (fig. 1). Among the investigations on the early stages of Hippa talponida, Say, were published in 1877.

With regard to the accessions to knowledge in the enormous group of the genuine Maerura, reference need only be made to the extensive reports in which Spence Bate, S. I. Smith, Faxon, Wood-Mason, Alcock, and others have made known the results of celebrated explorations. Various larval stages have been successfully investigated by Sars. Alcock (1901) describes from his own observation the newly hatched Phyllospora larva of Temora orientalis, Fabricius. An admirable discrimination of the larval and adult characters of the genus Sergestes has been given by H. J. Hansen (Proc. Zool. Soc., London, 1886). Singularity excites our wonder in Thaumastochelis malacca, v. Willemoes Suhm, which makes up for its vanished eyes by its extraordinarily elongate and dentated claws; in Psalidopus auxleyi, Wood-Mason and Alcock (1892), bristling with spines from head to tail; in the Nematocerinae, with their long thread-like lumbar antennae; in species of Aristeaspis reported by Chunn from deep water off the east coast of Africa, bright red prawns nearly a foot long, with antennae about five times the length of the body. That certain species, particularly many from deep water, have disportionately large eyes, is explained by the supposition that the young derive the advantage of being hatched in an advanced stage of development.

**Fig. 2.** Anaspides tasmaniae, Thomson.

**Fig. 3.** Pseudocuma pectinatum, Sowinsky.

eminent naturalists were still debating whether in this group there were eyes or no eyes, whether the eyes were stalked or sessile, whether the animals observed were larval or adult. The American T. Say in 1817, 

**Fig. 2.** Anaspides tasmaniae, Thomson.

**Fig. 3.** Pseudocuma pectinatum, Sowinsky.
the carapace is much more developed in the comparatively sedentary female than in the usually more active male. Only in the male do the second antennae attain considerable length, with strong resemblance to what is found in some of the Amphipoda. About 150 species distributed among thirty-four genera are now known, many from shallow water and from between tide-marks, some from very great depths. H. J. Hansen concludes that “they are all typically ground animals, and as yet no species has been taken under such conditions that it could be reckoned to the pelagic plankton.” As they have been found in all zones and chiefly by a very few observers, it is probable that a great many more species remain to be discovered. In recent years thirteen species, all belonging to the genus Pseudocaena (fig. 9), have been recorded by Sars from the Caspian Sea. A bibliography of the order is given in that author’s *Crustacea of Norway*, vol. iii. (1899–1900).

6. Isopora.—This vast and populous order can be traced far back in geological time. It is now represented in all seas and lands, in fresh-water lakes and streams, and even in warm springs. It adapts itself to parasitic life not only in fishes, but in its own class Crustacea, and that in species of every order, its own included. In this process changes of structure are apt to occur, and sometimes unimaginable sacrifices of the normal appearance. This has been divided into seven tribes, of which a fuller summary than can here be given will be found in Stebbing, *History of Crustacea* (1893). The first tribe, called Chelilla, from the usual chelate or claw-like condition of the dactyls, may be regarded as Isopora anomala. In the latter the carapace has been divided into seven segments, of which some would authors form a separate order, Tanaidea. Like the genuine isopods, they have seven pairs of trunk-legs, but instead of having seven segments of the middle body (or peraeon) many essential works on this group may be named the *Monograph of Schönherr and Meine* (1879–1883); “Challenger” Report, 1884–1886; *Carolloides*, H. J. Hansen (1890); *Isopora terrestria*, Buddle-Lund (1882); *Byrdeida*, Bonnier (1900); *Crustacea of Norway*, vol. ii. (1899); *Sars* (1890–1899), while the latter two provide a comprehensive account of important contributions by Benedict, Boisblanc, Chilton, Dorn, Dolfus, Fries, and Bonnier, Hargreaves, Hassel, Kossman, Miers, M. Murdock, Norman, Hassel, Walkover, C. M. Thomson, A. O. Walker, Max Weber and many others.

7. Amphipoda.—As in the genuine Isopoda, the eyes of Amphipoda are always sessile, and generally paired, and, in contrast to Crustacea, the first two pairs of mouth-organs are in the middle of the body, the more or less simple branchial vessels being attached to some or all of the coxal legs. Normally the penne carries six pairs of two-branched appendages, of which the first three are much articulated flexible swimming feet, the last three of unequal, comparatively indurated urapods. There are three tribes, Gammaridae, Caprellidae, Hyperiederidae. The small middle one contains but two families, the cylindrical and often thread-like shrimp-like Crustacea, and their near cousins, the broad, flattened, so-called whale-lip, Caprellidae. This tribe has been traced to the ancient Cambrian and is characterized by an intimate interlacing of characters, and forms a compact whole at present defying intrusion from any other crustacean group. Since 1775, when J. C. Fabricius instituted the genus *Gammarus* for terrestrial isopods, of which there were few, the amphipods, while he left five other amphipods in the genus *Onisca*, from this total of eight science has developed the order, at first very slowly, but by great leaps and bounds, so that now the Gammaridae alone comprise more than 1,500 species, distributed among some 500 genera and 90 families, or orders. They burrow in the sands and shells of every shore; they ascend from the depths of the sea; they live in the fresh waters and in the lakes and streams, and even in the warm springs. They are free, breathing the air, and are a very large order, as much as a tenth of an inch long, with their eyes-covered head; the *Rhabdosoma*, like a thin rod of glass, with needle-like head and tail, large eyes, but limbs and mouth-organs all in miniature, and the second antennae of the male, forming a very distinct organ, which male is characterized by a few slender legs and not by the usual features of the female. A great many, of these species of Rhabda and their kindred, so fat and wholesome that they have been commended to shipwrecked men in open boats as an easily procurable resource against starvation. Many of the amphipods are salt-water forms. Some of them are even carnivorous. The Caprellidae affect the giant whale while it lies aspical, and the *Chlora terabrobus* is destructive to submerged timber. But, on the other hand, they largely help to clear the sea and other waters of refuse and carrion, and for fishes, seals and whales they are a desirable and often astoundingly copious. From the salt-}
Andalusian plain watered by the Guadalquivir, the southern is mountainous, and rises steeply from the coast. Of the numerous sierras, the Alhamilla is a notable one; and at one point rising above 7000 ft.; its westward continuation in the Sierra de Abdalajis and the Axarquia between Antequera and Malaga; and not far from the Cadiz boundary the Sierras de Ronda, de Mijas, de Tolox and Bermeja, converging and culminating in a summit of nearly 6500 ft. The rivers which rise in the watershed formed by all these ranges reach the sea after a short and precipitous descent, and in rainy seasons are very liable to overflow their banks. In 1907 great loss of life and destruction of property were caused in this manner. The principal river is the Guadalhorce, which rises in the Sierra de Alhama, and, after a westerly course past the vicinity of Antequera, bends southward through the wild defile of Peñarrubia and the beautiful Vega de Malaga, falling into the sea near that city. The only other considerable stream is the Guadalete, which has the greater part of its course within the province, and flows past Ronda. There is an extensive salt lagoon near the northern boundary. The mountains are rich in minerals, lead, and (in the neighbourhood of Marbella) iron, being obtained in large quantities. There are warm sulphurous springs and baths at Carraatraca. Though the methods of agriculture are for the most part rude, the yield of wheat in good seasons is considerably in excess of the local demand; and large quantities of grapes and raisins, oranges and lemons, figs and almonds, are annually exported. The oil and wines of Malaga are also highly esteemed, and after 1870 the manufacture of beet and cane sugar developed into an important industry. In 1905 there were about 350 flour mills and 250 oil factories beside 95 stills and 100 wine-presses in the province. Malaga has suffered severely from the agricultural depression prevalent throughout southern Spain, but its manufacturing industries tend to expand. The fisheries are important; a fleet of about 300 boats brings in 18,000,000 lb annually, of which 25% is exported. The internal communications are in many parts defective, owing to the broken nature of the surface; but the province is traversed from north to south by the Cordova-Malaga railway, which sends off branches from Bobadilla to Granada and Algeciras. A branch line along the coast from Malaga to Vélez-Malaga was opened in 1908.

Malaga, the capital (pop. 130,109), Antequera (31,609), Vélez-Malaga (23,586), Ronda (20,995), Coín (12,326), and Alora (10,325), are the leading towns of the province. In Malaga city, with about 7000 inhabitants are Marbella (3629), Estepona (9310), Arcidona (8880) and Nerja (7112). The population of the province tends gradually to decrease, as many families emigrate to South America, Algeria and Hawaii.

MALAGA, the capital of the province of Malaga, an episcopal see, and próximo to Barcelona, the most important seaport of Spain, finely situated on the Mediterranean coast, at the southern base of the Axarquia hills and at the eastern extremity of the fertile Vega (plain) of Malaga in 36° 43' N. and 4° 25' W. Pop. (1900), 130,109. From the clearness of its sky, and the beautiful sweep of its bay, Malaga has sometimes been compared with Naples. The climate is one of the mildest and most equable in Europe, the mean annual temperature being 66° Fahr. The principal railway inland gives access through Bobadilla to all parts of Spain, and a branch line along the coast to Vélez-Malaga was opened in 1908. Malaga lies principally on the left bank of a mountain torrent, the Guadalmedina ("river of the city"); the streets near the sea are spacious and comparatively modern, but those in the older part of the town, where the buildings are huddled around the ancient citadel, are narrow, winding and often are cut off by the defiles of the mountains, which extend sides into the rich and pleasant country which surrounds Malaga, and several acres of land reclaimed from the sea have been converted into a public park. There are various squares or plazas and public promenades; of the former the most important are the Plaza de Riego (containing the monument to General José María Torrijos, who, with forty-eight others, was executed in Malaga on the 11th of December 1831, for promoting an insurrection in favour of the constitution) and the Plaza de la Constitución; adjoining the quays is the fine Paseo de la Alameda. The city has no public buildings of commanding architectural or historical importance. The cathedral, on the site of an ancient mosque, was begun about 1528; after its construction had been twice interrupted, it was completed to its present state in the 18th century, and is in consequence an obtrusive record of the degeneration of Spanish architecture. The woodwork of the choir, however, is worthy of attention. The church of El Cristo de la Victoria contains some relics of the siege of 1487. There are an English church and an English cemetery, which dates from 1830; up to that year all Protestants who died in Malaga were buried on the foreshore, where their bodies were frequently exposed by the action of wind and sea. Of the old Moorish arsenal only a single horse-shoe gateway remains, the rest of the site being chiefly occupied by an iron structure used as a market; the Alcazaba, or citadel, has almost disappeared. The castle of Gibralbaro, on a bold eminence to the north-west, dates from the 13th century, and is still in fairly good preservation.

During the 19th century so much silt accumulated in the harbour that vessels were obliged to lie in the roads outside, and receive and discharge cargo by means of lighters; but new harbour works were undertaken in 1880, and large ships can now again load or discharge at the quays, which are connected with the main railway system by a branch line. About 2150 ships of 1,750,000 tons entered at Malaga every year. Iron, lead, wine, olive oil, almonds, fresh and dried fruit, palmot and canary seed are exported in large quantities, while the imports include grain, codfish, fuel, chemicals, iron and steel, machinery, manures and staves for casks. Although trade was impeded during the early years of the 20th century by a succession of bad harvests and by the disastrous floods of September 1907, the number of industries carried on in and near Malaga tends steadily to increase. There are large cotton mills, iron foundries, smithing works and engineering works. Pottery, mosaic, artificial stone and tiles are produced chiefly for the home market, though smaller quantities are sent abroad. There is a chromo-lithographic establishment, and the other industries include tanning, distilling and the manufacture of sugar, chocolate, soap, candles, artificial ice, chemical products, white lead and pianos. Foreign capital has played a prominent part in the development of Malaga; a French syndicate owns the gas-works, and the electric lighting of the streets is controlled by British and German companies.

Malaga is the Málaxa of Strabo (iii. 156) and Ptolemy (ii. 4, 7) and the Malaca foedatorum of Pliny (iii. 3). The place seems to have been of some importance even during the Carthaginian period; under the Romans it became a municipium, and under the Visigoths an episcopal see. In 711 it passed into the possession of the Moors, and soon came to be regarded as one of the most important cities of Andalusia. It was attached to the Caliphate of Cordova, but on the fall of the Omayyad dynasty it became for a short time the capital of an independent kingdom; afterwards it was dependent on Granada. In 1489 it was taken and treated with great harshness by Ferdinand and Isabella after a protracted siege. In 1810 it was sacked by the French under General Sebastiani. The citizens of Malaga are noted for their opposition to the Madrid government; they took a prominent part in the movements against Espartero (1843), against Queen Isabella (1868) and in favour of a republic (1873).

MALAKAND PASS, a mountain pass in the North-West Province of India, connecting the British district of Peshawar with the Swat Valley. It is now a military post and the headquarters of a political agency. It came into prominence for the first time in 1895 during the Chitral campaign, when 7000 Pathans held it against Sir Robert Low's advance, but were easily routed. After the campaign was over a fortified camp was formed on the Malakand to guard the road to Chitral. During the frontier risings of 1897 the Swatis made a determined attack on the Malakand, where 700 were killed, and on the adjacent post of Chakdara, where 2000 were killed. This was the origin of the Malakand Expedition of the same year. (See SWAT.)
MALALAS—MALALAS

MALALAS (or MALELAS) (Syrac for “orator”), JOHN (c. 491-578). Byzantine chronicler, was born at Antioch. He wrote a Χειρόγραφον in 18 books, the beginning and the end of which are lost. In its present state it begins with the mythical history of Egypt and ends with the expedition to Africa under Marcianus, the nephew of Justinian. Except for the history of Justinian and his immediate predecessors, it possesses little historical value; it is written without any idea of proportion and contains astonishing blunders. The writer is a supporter of Church and State, an upholder of monarchical principles. The work is rather a chronicle written round Antioch, which he regarded as the centre of the world, and (in the later books) round Constantinople. It is, however, important as the first specimen of a chronicle written not for the learned but for the instruction of the monks and the common people, in the language of the vulgar, with an admixture of Latin and Oriental words. It obtained great popularity, and was conscientiously exploited by various writers of Oriental, 17th century, being translated even into the Slavonic languages. It is preserved in an abridged form in a single MS. now at Oxford.

For the authorities consulted by Malalas, the influence of his work on Slavonic and Oriental literature, the state of the text, the original form and extent of the work, the date of its composition, the relation of the concluding part to the whole, and the literature of the immediate predecessors, see his Geschichte der Litteratur (1897). See also the editio princeps, by E. Chilmead (Oxford, 1691), containing an essay by Humphrey Hody and Bentley’s well-known letter to Mill; other editions in the Bonn Caes., Scriptum, etc., etc., by L. Dindorf (1831), and in J. P. Migne Patrologia graeca, xviii.

MALAN, SOLOMON CAESAR (1812-1894), British divine and orientalist, was by birth a Swiss descended from an exiled French family, and was born at Geneva on the 22nd of April 1812, where his father, Dr Henry Abraham Caesar Malan (1787-1864) enjoyed a great reputation as a Protestant divine. From his earliest youth he manifested a remarkable faculty for the study of languages, and when he came to Scotland as tutor in the marquis of Tweeddale’s family at the age of 18 he had already made progress in Sanskrit, Arabic and Hebrew. In 1833 he matriculated at St Edmund Hall, Oxford; and English being almost an unknown tongue to him, he petitioned the examiners to allow him to do his paper work of the examination in French, German, Spanish, Italian, Latin or Greek, rather than in English. But his request was not granted. After gaining the Boden and the Pusey and Ellerton scholarships, he graduated 2nd class in Lit. hum. in 1837. He then proceeded to India as classical lecturer at Bishop’s College, Calcutta, to which post he added the duties of secretary to the Bengal branch of the Royal Asiatic Society; and although compelled by illness to return in 1840, laid the foundation of a knowledge of Tibetan and Chinese. After serving various curacies, he was presented in 1845 to the living of Bledington, Dorset, which he held until 1860. During this entire period he continued to augment his linguistic knowledge, which he carried so far as to be able to preach in that most difficult language, Georgian, on a visit which he paid to Ninveh in 1872. His translations from the Armenian, Georgian and Coptic were numerous. He applied his Chinese learning to the determination of important points connected with Chinese religion, and published a vast number of parallel passages illustrative of the Book of Proverbs. In 1880 the university of Edinburgh conferred upon him the honorary degree of D.D. No modern scholar, perhaps, has so nearly approached the linguistic omniscience of Mezzofanti; but, like Mezzofanti, Dr Malan was more of a linguist than a critic. He made himself conspicuous by the vehemence of his opposition to Westcott and Hort’s text of the New Testament, and to the transliteration of Oriental languages, on neither of which points did he in general obtain the suffrages of scholars. His extensive and valuable library, some special collections excepted, was presented by him in his lifetime to the Indian Institute at Oxford. He died at Bournemouth on the 25th of November 1894. His life has been written by his son.

MALAR, a lake of Sweden, extending 73 m. westward from Stockholm, which lies at its junction with the Saltcjö, an arm of the Baltic Sea. The height of the lake is normally only from 11 ft. to 2 ft. above sea-level, and its outflow is sometimes regulated. The area is 449 sq. m. The bottom consists of a series of basins separate by ridges from which rise numerous islands. The deepest sounding is 210 ft. The outline is very irregular, the mean breadth being about 15 m., but an arm extends northward for 30 m. nearly to the city of Upsala with many ramifications. The area of the drainage basin is 8789 sq. m., of which 1124 are occupied by lakes. The navigable connexion with the lake are—(1) with lake Hjelmär the south-west by the Arboga river and the Hjelmär canal; and by the Eskilstuna river and the Thorshälla canal; (2) with the Baltic southward through the Södertelge canal, the route followed by the Göta canal steamers; (3) with the Baltic by two channels at Stockholm. The more important towns, besides Stockholm, are Vsteras on the north, Södertelge and Eskilstuna near the south shore. This lake offers a field for recreation fully appreciated by the inhabitants of the capital, and many of those whose business lies at Stockholm have their residences on the shores of Malar. On Drottningholm (Queen’s Island, named from Catherine, wife of John III.) is a palace with a fine park and formal gardens. John III. built a palace at the close of the 16th century, but the existing building, by Nicodemus Tessin and his son Nicodemus, dates from the second half of the 17th century. At Malerfjord on the south shore there is the castle of Gripsholm (1357), built by Gustavus Vasa, a picturesque erection with four towers, richly adorned within, and containing a large collection of portraits. Strengnäs, on the same shore, became an episcopal see in 1291, when the fine cathedral, much altered since, was consecrated. In the episcopal building, a palace of the 15th century now used as a school, Gustavus Vasa was elected to the throne of Sweden in 1523. On the northward arm of the lake is the palace of Rosenborg, used as a school of gunnery in a well-wooded park. On a branch of the same arm is Sigtuna, a village whose ruined churches are a memorial of its rank reversed, and the principal towns of Sweden after its foundation in the 11th century. Remains prove that on Björkö, an island in the eastern part of the lake, there was a large settlement of earlier importance than Sigtuna. Here a cross commemorates the preaching of Christianity by St Ansgar in 829. Finally, on the southern arm about 10 m. south of Upsala, there is the chateau of Skokloster, occupying the site of a monastery, and presented by Gustavus Adolphus to Marshal Herman Wrangel, whose son Charles Gustavus Wrangel stored it with a remarkable collection of trophies from Germany, taken during the Thirty Years’ War; including a library, an armoury, and a great accumulation of curios.

MALARIA, an Italian colloquial word (from mala, bad, and aria, air), introduced into English medical literature by Macculloch (1827) as a substitute for the more restricted terms “marsh miasm” or “paludal poison.” It is generally applied to the definite unhealthy condition of body known by a variety of names, such asague, intermittent (and remittent) fever, marsh fever, jungle fever, hill fever, “fever of the country” and “fever and ague.” A single paroxysm of simple ague may come upon the patient in the midst of good health or it may be preceded by some malaiae. The ague-fit begins with chills proceeding as if from the lower part of the back, and gradually extending until the coldness overtakes the whole body. Tremors of the muscles more or less violent accompany the cold sensations, beginning with the muscles of the lower jaw (chattering of the teeth), and extending to the extremities and trunk. The expression has meanwhile changed: the face is pale or livid; there are dark rings under the eyes; the features are pinched and sharp, and the whole skin shrunk; the fingers are dead white, the nails blue.

All these symptoms are referable to spasmodic constriction of the small surface arteries, the pulse at the wrist being itself small, hard and quick. In the interior organs there are indications of a compensating accumulation of blood, such as swelling of the spleen, engorgement (very rarely rupture) of the heart,
with a feeling of oppression in the chest, and a copious flow of clear and watery urine from the congested kidneys. The body temperature will have risen suddenly from the normal to 105° or higher. This first or cold stage of the paroxysm varies much in length; in temperate climates it lasts from one to two hours, while in tropical and subtropical countries it may be shortened. It is followed by the stage of dry heat, which will be prolonged in proportion as the previous stage is curtailed. The feeling of heat is at first an internal one, but it spreads outwards to the surface and to the extremities; the skin becomes warm and red, but remains dry; the pulse becomes softer and more full, but still quick; and the throbings occur in exposed arteries, such as the temporal. The spleen continues to enlarge; the urine is now scanty and high-coloured; the body temperature is high, but the highest temperatures occur during the chill; there is considerable thirst; and there is the usual intellectual unfitness, and it may be confusion, of the feverish type of apyrexia. Red heat, having lasted three or four hours or longer, comes to an end in perspiration, at first a mere moistness of the skin, passing into sweating that may be profuse and even drenching. Sleep may overtake the patient in the midst of the sweating stage, and he awakes, without some feeling of what he has passed through, but on the whole well, with the temperature fallen almost or altogether to the normal, or it may be even below the normal; the pulse moderate and full; the spleen again of its ordinary size; the urine that is passed after the paroxysm deposits a thick brick-red sediment of urates. The three stages together will probably have lasted six to twelve hours. The paroxysm is followed by a definite interval in which there is not only no fever, but even a fair degree of bodily comfort and fitness; this is the intermission of the fever. Another paroxysm begins at or near the same hour next day (quotidian ague), which results from a double tertian infection, or the interval may be four, eight hours (tertian ague), or seventy-two hours (quartan ague). It is the general rule, with frequent exceptions, that the quotidian paroxysm comes on in the morning, the tertian about noon, and the quartan in the afternoon. Another rule is that the quartan has the longest cold stage, while its paroxysm is shortest as a whole; the quotidian has the shortest cold stage and a long hot stage, while its paroxysm is longest as a whole. The point common to the various forms of ague is that the paroxysms cease about midnight or early morning. Quotidian intermittent is on the whole more common than tertian in hot countries; elsewhere the tertian is the usual type, and quartan is only occasional.

If the first paroxysm should not cease within the twenty-four hours, the fever is not reckoned as an intermittent, but as a remittent or tertian ague.

Remittent is not an unusual form of the malarial process in tropical and subtropical countries, and in some localities or in some seasons it is more common than intermittent. It may be said to arise out of the last intermittent in which the cold stage is shorter than the fever, the hot stage tends to be prolonged. A certain abatement or remission of the fever takes place, with or without sweating, but there is no true intermission or interval of absolute apyrexia. The period of the short type of tertian and of quartan ague is the same and would cover the usual continuance of the ague, and that exacerbation may take place twenty-four hours after the first onset, or the interval may be only half that period, or it may be double. A fever that is to be remittent will be remittent from the very beginning, without any transition over the common ague. Towards morning the fever abates; the pulse falls in frequency, but does not come down to the normal; headache and aching in the loins and limbs become less, but do not cease; and the patient may believe himself better; but diarrhœa may follow. The patient may wake up as if his fever was over, but the remission or abatement lasts generally throughout the morning; and about noon there is an exacerbation, seldom ushered in by chills, which continues till the early morning following, when the fever subsides. A remittent fever may get well in a week under treatment, but the fever may go on for several weeks; the return to health is often announced by the fever assuming the intermittent type, or, in other words, by the remissions tending to become intervals. The fever, as well as intermittent, varies considerably in intensity; some cases are intense from the outset, or pernicious, with aggravation of all the symptoms—leading to stupor, delirium, collapse, intense jaundice, blood in the stools, blood and albumen in the urine, and, it may be, suppression of urine followed by convulsions. The severe forms of intermittent are most apt to occur in the very young, in the aged, or in debilitated persons generally. Milder cases of malarial fever are apt to become dangerous from the complications of dysentery, bronchitis or pneumonia. Severe remittents (pernicious or bilious remittents) approximate to the ordinary yellow fever (q.v.), which is convoluted by the epidemics which occur in western longitudinal on and west coast of Africa.

Of the mortality due to malarial disease a small part only is referable to the direct attack of intermittent, and chiefly to the fever in its pernicious form. Remittent fever is much more fatal in its direct attack. But probably the greater part of the enormous total of deaths set down to malaria is due to the malarial cachexia. The dwellers in a malarious region like the Teral (at the foot of the Himalayas) are miserable, ill and ugly, with large heads and particularly prominent ears, flat noses, rudimentary, small and hollow complexes; the children are impregnated with malaria from their birth, and their growth is attended with aberrations from the normal which practically amount to the disease of rickets. The malarial cachexia which follows definite attacks of ague consists in a state of ill-defined suffering, associated with a sallow skin, enlarged spleen and liver, and sometimes with dropsy.

Causation.—From the time of Hippocrates onwards the malarial or periodic fevers have engaged the attention of innumerable observers, who have suggested various theories of causation, and have sometimes anticipated—vaguely, indeed, but with surprising accuracy—the results of modern research; but the true nature of the disease remained in doubt until the closing years of the 19th century. It has now been established by a series of accurate investigations, contributed by many workers, that malaria is caused by a microscopic parasite in the blood, into which it is introduced by the bites of certain species of mosquito. (See Parasitic Diseases and Mosquitoes.)

The successive steps by which the present position has been reached form an interesting chapter in the history of scientific progress. The first substantial link in the actual chain of discovery was contributed in 1880 by Laveran, a French army surgeon serving in Algeria. On the 6th of November in that year he plainly saw the living parasites under the microscope in the blood of a malarial patient, and he shortly afterwards communicated his observations to the Paris Académie de Médecine. They were confirmed, but met with little acceptance in the scientific world, which was preoccupied by the claims of a subsequently discredited Italian pathologist, Giovanni Battista Grassi, and of the French, Landry and Golgi, who still held to the old theory of the malarial fever being caused by a morbus cachexia. In 1883 the Italian pathologists came round to Laveran's views, and began to work out the life history of his parasites. The subject has a special interest for Italy, which is devastated by malaria, and Italian science has contributed materially to the solution of the problem. The labours of Golgi, Marchiafava, Celli and others established the nature of the parasite and its behaviour in the blood; they proved the fact, guessed by Rasori so far back as 1846, that the periodical febrile paroxysm corresponds with the development of the organisms; and they showed that the different forms of malarial fever have their distinct parasites, and consequently fall into distinct groups, defined on an etiological as well as a clinical basis—namely, the mild or spring group, which includes tertian and quartan ague, and the malignant or "aestivo-autumnal" group, which includes a tertian or a semi-tertian and the true quotidian ague. Following with the tertian, quartan and malignant types of fever, have been described by Italian observers, and the classification is generally accepted; intermediate types are ascribed to mixed and multiple infections.

So far, however, only half the problem, and from the practical point of view the least important half, had been solved. The origin of the parasite and its mode of introduction into the blood remained to be discovered. An old popular belief current in different countries, and derived from common
observation, connected mosquitoes with malaria, and from time to time this theory found support in more scientific quarters on general grounds, but it lacked demonstration and attracted little attention. In 1894, however, Sir Patrick Manson, arguing with greater precision by analogy from his own discovery of the cause of filariasis and the part played by mosquitoes, suggested that the malarial parasite had a similar intermediate host outside the human body, and that a sectorial insect, which would probably be found to be a particular mosquito, was required for its development. Following up this line of investigation, Major Ronald Ross in 1895 found that if a mosquito sucked blood containing the parasites they soon began to throw out flagellae, which broke away and became free; and in 1897 he discovered peculiar pigmented cells, which afterwards turned out to be the parasites of aestivo-autumnal malaria in an early stage of development, within the stomach-wall of mosquitoes which had been fed on malarial blood. He further found that only mosquitoes of the genus Anopheles had these cells, and that they did not get them when fed on healthy blood. Then, turning his attention to the malaria of birds, he worked out the life-history of these cells within the body of the mosquito. “He saw that they increased in size, divided, and became full of filiform spores, then ruptured and poured out their multiditudinous progeny into the body-cavity of their insect host. Finally, he saw the spores accumulate within the cells of the salivary glands, and discovered that they actually passed down the salivary ducts and along the grooved hypopharynx into the seat of puncture, thus causing infection in a fresh vertebrate host” (Sambon). To apply these discoveries to the malaria of man was an obvious step. In working out the details the Italian school have again taken a prominent part.

Thus we get a complete scientific demonstration of the causation of malaria in three stages: (1) the discovery of the parasite in its normal cycle and connection with the fever demonstrated by the Italian observers; (2) its life-history in the human host and correlation with the fever demonstrated by the Italian observers; (3) its life-history in the alternate host, and the identification of the latter with a particular species of mosquito by Ross and Manson. The conclusions derived from the microscopical laboratory were confirmed by actual experiment. In 1898 an experiment, it was conclusively shown in Italy that if a mosquito of the Anopheles variety bites a person suffering from malaria, and is kept long enough for the parasite to develop in the salivary gland, and is then allowed to bite a healthy person, the latter will in due time develop malaria. The converse proposition, that persons efficiently protected from mosquito bites escape malaria, has been made the subject of several remarkable experiments. One of the most interesting was carried out in 1900 for the London School of Tropical Medicine by Dr Sambon and Dr Low, who went to reside in one of the most malarious districts in the Roman Campagna during the most dangerous season. Together with Signor Terzi and two Italian servants, they lived from the beginning of July until the 19th of October in a specially protected hut, erected near Ostia. The sole precaution taken was to confine themselves between sunset and sunrise to their mosquito-proof dwelling. All escaped malaria, which was rife in the immediate neighbourhood. Mosquitoes caught by the experimenters, and sent to London, produced malaria in persons who submitted themselves to the bites of these insects at the London School of Tropical Medicine. Experiments in protection on a larger scale, and under more ordinary conditions, have been carried out with equal success by Professor Celli and other Italian authorities. The first of these was in 1899, and the subjects were the railwaymen employed on certain lines running through highly malarious districts. Of 24 protected persons, all escaped but four, and these had to be put at fault for either negligence or neglect. Of 38 unprotected persons, all contracted malaria except two, who had apparently acquired immunity. In 1900 further experiments gave still better results. Of 52 protected persons on one line, all escaped except two, who were careless; of 52 protected on another line, all escaped; while of 51 unprotected persons, living in alternate houses, all suffered except seven. Out of a total of 207 persons protected in these railway experiments, 107 escaped. In two peasants’ cottages in the Campagna, protected with wire netting by Professor Celli, all the inmates—ten in number—escaped, while the neighbours suffered severely; and three out of four persons living in a third hut, from which protection was removed owing to the indifference of the inmates, contracted malaria. In the malarious islet of Asinara a pond of stagnant water was treated with petroleum and all windows were protected with gauze. The result was that the houses were free from mosquitoes and no malaria occurred throughout the entire season, though there had been 40 cases in the previous year. Eight Red Cross ambulances, each with a doctor and attendant, were sent into the most malarious parts of the Campagna in 1900. By living in protected houses and wearing gloves and veils at night all the staff escaped malaria except one or two attendants. These and other experiments, described by Dr Manson in the Prac titioner for March 1900, confirming the laboratory evidence as they do, leave no doubt whatever of the correctness of the mosquito-parasitic theory of malaria.

It is possible, though not probable, that malaria may also be contracted in some other way than by mosquito bite, but there are no well-authenticated facts which require any other theory for their explanation. The alleged occurrence of the disease in localities free from mosquitoes or without their agency is not well attested; its absence from other localities where they abound is accounted for by their being of an innocent species, or—as in England—free from the parasite. The old theory of paludism or of a noxious miasma exhaled from the ground is no longer necessary. The broad facts on which it is based are sufficiently accounted for by the habits of mosquitoes. For instance, the swampy character of malarious localities is explained by their breeding in stagnant water; the effect of drainage and the general immunity of high-lying, dry localities, by the lack of breeding facilities; the danger of the night air, by their nocturnal habits; the comparative immunity of the upper storeys of houses, by the fact that they fly low; the confinement of malaria to well-marked areas and the diminution of danger with distance, by their habit of clinging to the breeding-grounds and not flying far. Similarly, the subsidence of malaria during cold weather and its seasonal prevalence find an adequate explanation in the conditions governing insect life. At the same time it should be remembered that many points await elucidation, and it is unwise to assume conclusions in advance of the evidence.

With regard to the parasites, which are the actual cause of malaria in man, an account of them is given under the heading of Parasitic Diseases, and little need be said about them here. Some are also very interesting, as one whole class of Anophelines, the genus Anopheles, which was first classified by Mi c e n in 1818. It has a wide geographical distribution, being found in Europe (including England), Asia Minor, Burma, Straits Settlements, Java, China, Formosa, Egypt, Australia, South America, West Indies, United States and Canada, but is generally confined to local centres in those countries. About fifty species are recognized at present. It is believed that all of them may serve as hosts of the parasite. The species best known in connexion with malaria are A. maculipennis (Europe and America), A. funestus
MALARIA

and A. costales (Africa). In colour Anopheles is usually brownish or slaty, but sometimes buff, and the thorax frequently has a dark line on each side. The wings in nearly all species have a dappled or speckled appearance, owing to the occurrence of blotches on the front margin and to the arrangement of the scales covering the veins in alternating light and dark patches (Austen). The genus with which Anopheles is most likely to be confounded is Culex, which is the commonest of all mosquitoes, has a world-wide distribution, and is generally a greedy blood-sucker. A distinctive feature is the position assumed in resting; Culex has a humpbacked attitude, while in Anopheles the proboscis, head and body are in a straight line, and in many species inclined at an angle to the wall, the tail sticking outwards. In the female of Culex the palpi are much shorter than the proboscis; in Anopheles they are of the same length. The wings in Culex have not the same dappled appearance. Anopheles is also a more slender insect, with a smaller head, narrower body and thinner legs. There are further differences in the other stages of life. Mosquitoes go through four phases: (1) ovum, (2) larva, (3) nympha, (4) complete insect. The ova of Anopheles are tiny black rod-shaped objects, which are deposited on the water of natural puddles, ponds, or slowly moving streams, by preference those which are well supplied with vegetation; they float, singly or attached to other objects or clustered together in patterns. They can live in brackish and even in sea water. The larva has no breathing-tube, and floats horizontally at the surface, except when feeding; it does not frequent sewage or foul water. The ova of Culex, on the other hand, are deposited in any stagnant water, including cesspools, drains, cisterns, or water collected in any vessel; they float in boat-shaped masses on the surface. The larva has a breathing-tube, and floats head downwards; when disturbed it wrinkles to the bottom (Christy). Some observers maintain that Anopheles does not "sing," like the common mosquito, and its bite is much less irritating. Only the females suck blood; the act is believed to be necessary for fertilization and reproduction. Anopheles rarely bites by day, and then only in dark places. In the daytime "the gorged females rest motionless on the walls and ceilings of rooms, choosing always the darkest situations for this purpose" (Austen). In temperate climates the impregnated females hibernate during the winter in houses, cellars, stables, the trunks of trees, &c., coming out to lay their eggs in the spring. The four phases are passed in thirty days in a favourable season, and consequently there are ordinarily four or five generations from April to September (Celli).

Three most important questions raised by the mosquito-parasitic theory of malaria are that of prevention. This may be considered under two heads: (1) individual prophylaxis; (2) administrative prevention on a large scale.

In the first place, common sense suggests the avoidance, in malarious countries, of unhealthy situations, and particularly the neighbourhood of stagnant water. Among elements of unhealthiness next is to be reckoned the proximity of native villages, the inhabitants of which are infected. In the tropics "no European house should be located nearer to a native village than half a mile" (Manson), and, since children are almost universally infected, "the presence of young natives in the house should be absolutely interdicted" (Manson). When unhealthy situations cannot be avoided, they may be rendered more healthy by destroying the breeding-grounds of mosquitoes in the neighbourhood. All stagnant water should be filled in or drained; as a temporary expedient they may be treated with petrol, which prevents the development of the larvae. When a place cannot be kept free from mosquitoes the house may be protected, as in the experiments in Italy, by wire gauze at the doors and windows. The arrangement used for the entrance is a wire cage with double doors. Failing such protection mosquito curtains should be used. Mosquitoes in the house may be destroyed by the fumes of burning sulphur or tobacco smoke. According to the experi-
The population of Ismailia is about 6000.

Klang and Port Swettenham are contiguous towns in the Federated Malay States, having a population of 4000 and a rainfall of 100 in. a year. At Klang the expenditure has been £1100, with an annual expenditure of £720, devoted to clearing and draining 332 acres. At Port Swettenham £7000, with an annual upkeep of £240, has been devoted to treating 110 acres. In Hong-Kong similar measures were carried out, with the result that the hospital admissions for malaria diminished from 1294 in 1901, the year when operations were begun, to 419 in 1905.

A systematic campaign for the destruction of breeding-places has been inaugurated in the British West African colonies, with encouraging results. The planting of eucalyptus trees is out of favour at present, but it appears to have been successful in Portugal, not from any prophylactic virtues in the plant, but through the great absorption of moisture by its deep roots, which tends to dry the subsoil. Treating the breeding-ponds with petroleum or similar preparations seems to be hardly applicable on a large scale, and in any case can only be a temporary expedient. H. Ziemann advocates the destruction of mosquito larvae by the growing of such plants as the water-pea (Anachoris alismatrum) which covers the surface of the water and suffocates larvae and nymphae. Short of suppressing mosquitoes, the parasitic cycle may theoretically be broken by preventing them from giving the infection to man or taking it from him. The means of accomplishing the former have been already pointed out, but they are obviously difficult to carry out on a large scale, particularly in native communities. It is one thing to prevent individuals from mosquito bites, another to prevent the propagation of the parasite in a whole community. Perhaps the converse is more feasible in some circumstances—that is to say, preventing mosquitoes from having access to malarial persons, and so propagating the parasite in themselves. It could be carried out where infected persons are few, by isolating and protecting them, but not where many are infected, as in native villages. Koch has suggested that the disinfection of malarial persons by quinine would have the desired effect, but other authorities of greater experience do not consider it practicable. In spite of the difficulties, however, there is no doubt that a great deal can be done to reduce, if not stamp out, malaria by the methods indicated, which should be applied according to circumstances. An encouraging example is afforded by the remarkable fact that malaria, which was once rife in certain districts of England, has now died out, although the Anopheles maculipennis mosquito still exists there. The parasitic cycle has been broken, and the insect is no longer infected. The suggested causes are (1) reduction of insects by drainage, (2) reduced population, (3) the use of quinine. Sir Patrick Manson has suggested that the problem of stamping out malaria may be assisted by the discovery of some at present unknown factors. He has pointed out that certain areas and certain islands are entirely free from the disease, while neighbouring areas and islands are devastated. This immunity is apparently not due to the absence of favourable conditions, but rather to the presence of some inimical factor which prevents the development of the parasite. If this factor could be discovered it might be applied to the suppression of the disease in malarious localities.

1 Drainage works begun.
2 Nearly all were relapses of previous infection.

MALATIA

A few other points may be noted. The pathological changes in malaria are due to the deposition of melanin and the detritus of red corpuscles and haemoglobin, and to the congregation of parasites in certain sites (Ross). In chronic cases the eventual effects are anaemia, melanosclerosis, enlargement of the spleen and liver, and general cachexia. Apparently the parasites may remain quiescent in the blood for years and may cause relapses by fresh sporulation. Recent discoveries have done little or nothing for treatment. Quinine still remains the one specific. In serious cases it should not be given in solid form, but in solution by the stomach, rectum, or—better—hypodermically (Manson). According to Ross, it should be given promptly, in sufficient doses (up to 30 grains), and should be continued for months. Equine is by some preferred to quinine, but it is more expensive. Nucleogen and Aristochin have also been recommended instead of quinine. The nature of immunity is not known. Some persons are naturally absolutely immune (Celli), but this is rare; immunity is sometimes acquired by infection, but as a rule persons once infected are more predisposed than others. Races inhabiting malarious districts acquire a certain degree of resistance, no doubt through natural selection. Children are much more susceptible than adults.

Malaria in the Lower Vertebrates.—Birds are subject to malaria, which is caused by blood parasites akin to those in man and having a similar life-history. Two species, affecting different kinds of birds, have been identified. Their alternate hosts are mosquitos of the Culex genus. Oxen, sheep, dogs, monkeys, bats, and probably horses also suffer from similar parasitic diseases. In the case of oxen the alternate host of the parasite is a special tick (Smith and Kilborne). In the other animals several parasites have been described by different observers, but the alternate hosts are not known.

MALATIA (MALATIÉ or ASPUZU) the chief town of a small area of the same name in the Mamuret el-Aziz vilayet of Asia Minor, and a military station on the Samsun-Sivas-Diabekr road, altitude 2000 ft., situated about 10 m. S.W. of the junction of the Tokhma Su (med. Kubakib) with the Euphrates, near the south end of a fertile plain, and at the northern foot of the Taurus. Pop. about 30,000, including, besides many Armenian Christians, bodies of Kurds and "Kizilbash." It is a wholly modern place, rebuilt since the earthquake of 1893, contains fine public buildings, and is noted for its fruit orchards. There are Protestant (American) and Roman Catholic missions, and an Armenian Catholic archbishop has his seat here. Eskishehr or Old Malatia (Melitene), 5 m. N.E. and 3 m. from the great medieval bridge (Kirkgeze) over the Tokhma Su, is said to owe its present desolation largely to its occupation by Hafiz Paşa as his base of operations in 1838, before his advent to fight the disastrous battle of Nizib with the Egyptian, Ibrahim. But it has still many inhabitants and large gardens and many ruinous mosques, baths, &c., relics of Mansur's city. It was the residence of von Moltke for some months, while attached to Hafiz's army. The earliest site was possibly Arslan Tepe about 2 m. south of Eskishehr were two "Hittite" steles, representing hunting scenes, now in the Constantinople and Paris museums, were found in 1894.

In the time of Strabo (xii. 537) there was no town in the district of Melitene, which was reckoned part of Cappadocia. Under Titus the place became the permanent station of the 12th ("Thundering") legion; Trajan raised it to a city. Lying in a very fertile country it was a post town on the Persian "Royal Road," and two imperial military highways from Caesarea along the Euphrates bank, it grew in size and importance, and was the capital of Armenia Minor or Secunda. Justinian, who completed the walls commenced by Anastasius, made it the capital of Armenia Tertia; it was then a very great place (Procop., De aed., iii. 4). The town was burnt by Chosroes on his retreat after his
great defeat there in 577. Taken by the Saracens, retaken and destroyed by Constantine Copronymus, it was presently recovered to Islam, and rebuilt under Mansur (A.D. 756). It again changed hands more than once, being reckoned among the frontier towns of Syria (Istakhri, pp. 55, 62). At length the Greeks recovered it in 934, and Nicephorus II, finding the district much wasted, encouraged the Jacobites to settle in it, which they did in great numbers. A convent of the Virgin, and the great church which bears his name, were erected by the bishop Ignatius (Isaac the Runner). From this time Malatia continued to be the chief seat of the Jacobites. and it was the birthplace of their famous maphrian Barhebraeus (or Abulfaragius). At the commencement of the 11th century the population was said to number 60,000 fighting men (Assem., Bib. Om. 140; cf. Barheb., Chron. Eccl., 411, 412). At the time of the first crusade, the city, being hard pressed by the Turks under Ibn Danishmend, was relieved by Baldwin, after Bohemund had failed and lost his liberty in the attempt. But the Jacobites had no chance of love by Byzantium, and the Greek government was so cruel and faithless that the townsmen were soon glad to open their gates to Ibn Danishmend (1102), and the city subsequently became part of the realm of Kilij Arslan, sultan of Iconium.

MALAYALAM, a language of the Dravidian family, spoken on the west coast of southern India. It is believed to have developed out of Tamil as recently as the 9th century. It possesses a large literature, in which words borrowed from Sanskrit are numerous. Indian place-name clusters of speakers of Malayalam in all India was just about six millions.

MALAY ARCHIPELAGO1 (variously called Malaysia, the Indian Archipelago, the East Indies, Indonesia, Insulindia), the largest group of islands in the world, lying south-east of Asia and north and north-west of Australia. It includes the Sunda Islands, the Moluccas, New Guinea, and the Philippine Islands, but excludes the Andaman-Nicobar group. The equator passes through the middle of the archipelago; it successively cuts Sumatra, Borneo, Celebes and Halmahera, four of the most important islands. A. R. Wallace (who includes the Solomon Islands as well as New Guinea in the group) points out that the archipelago "includes two islands larger than Great Britain; and in one of them, Borneo, the whole of the British Isles might be set down, and would be surrounded by a sea of forests. Sumatra is about equal in extent to Great Britain; Java, Luzon, and Celebes are each about the size of Ireland. Eighteen more islands are on the average as large as Jamaica; and more than a hundred are as large as the Isle of Wight." [Table]

The islands of the archipelago nearly all present bold and picturesque profiles against the horizon, and at the same time the character of the scenery varies from island to island and even from district to district. The mountains are arranged for the most part in lines running either from north-west to south-east or from west to east. In Sumatra and in the islands south of it there are usually sharp and broken mountain ranges distinctly marked, and the latter is equally noticeable in Java and the other southern islands. The mountains of Borneo, however, rise rather in short ridges and clusters. Nothing in the general physiognomy of the islands is more remarkable than the number and distribution of the volcanoes, active or extinct. Running south-east through Sumatra, east through Java and the southern islands to Timor, curving north through the Moluccas, and again north, from the end of Celebes through the whole line of the Philippines, they follow a line roughly resembling a horseshoe narrowed towards the point. The loftiest mountain in the archipelago would appear to be Kinabalu in Borneo (13,698 ft.). An important fact in the physical geography of the archipelago is that Java, Bali, Sumatra and Borneo, and the lesser islands between them and the Asiatic mainland, all rest on a great submerged bank, nowhere more than 100 fathoms below sea-level, which may be considered as a distinct ocean. But so far to the east the depth of the sea has been found at various places to be about 1,000 to 2,500 fathoms. As the value of this fact was particularly emphasized by Wallace, the limit of the shallow water, which is found in the narrow but deep channel between Bali and Lombok, and strikes north to the east of Borneo, has received the name of "Wallace's Line." The Philippines on the other hand, "are almost surrounded by deep sea, but are connected by Borneo by means of two narrow submarine banks" (A. R. Wallace, Island Life). The archipelago, in effect, is divided between two great regions, the Asiatic and the Australian, and the fact is evident in various branches of its geography—zoological, botanical, and even human. It is believed that there was a land-connection between Asia and Australia in the later part of the Secondary epoch, and that the Australian continent, when separated, became divided into islands before the south-eastern part of the Asiatic did so.

The most notable fact in the geological history of the archipelago is the discovery in Java of the fossil remains of Pithecanthropus erectus (Boule), a prehistoric man of large brain and robust physical type. In its structure and cranial capacity it is entitled to a higher place in the zoological scale than any anthropoid, for it almost certainly walked erect; and, on the other hand, in its intellectual powers it must have been much below the lowest of the human race at present known. The strata in which it was found belong to the Miocene or Upper Pliocene. Among the rocks of economic importance may be mentioned granite of numerous kinds, syenite, serpentine, porphyry, marble, and various clay deposits, including clay for tile-making in Sumatra, Borneo and Labuan. Diamonds are obtained in Borneo, garnets in Sumatra, Bachian and Timor, and topazes in Bachian, antiquity in Borneo and the Philippines; lead in Sumatra, Borneo and the Philippines; manganese in Sumatra, Borneo, Timor, and Borneo; and most important of all, tin in Banka, Billiton and Singkep. Iron is pretty frequent in various forms. Gold is not uncommon in the older ranges of Sumatra, Borneo and Celebes; Bachian, Timor and Borneo. Manganese could be readily worked in Timor, where it lies in the Carboniferous Limestone. Platinum is found in Landak and other parts of Borneo. Petroleum is a valuable product of Sumatra and Java, and is also found in Borneo.

Climate, Flora, Fauna.—The most striking general fact as regards climate in the archipelago is that wherever that part of the south-east monsoon which has passed over Australia strikes, the climate is comparatively dry, and the vegetation is less luxuriant than on the west of Java, and that a much drier climate than the west; the distribution of the rain on the north coast is quite different from that on the south, and a similar difference is observed between the east and the west of Celebes. The north-west monsoon, beginning in October and lasting till March, brings the principal rainy season in the archipelago.

Most of the islands of the archipelago belong to the great equatorial forest-belt. In its economical aspect the vegetation, whether natural or cultivated, is of prime interest. The list of fruits is very extensive, though few of them are widely known. These, however, include the orange, mango, mangosteen, shaddock, guava and the durian. The variety of food-plants is equally notable. Not only are rice and maize, sugar and coffee, among the widely cultivated crops, but the coco-nut, the bread-fruit, the banana and the bread-nut, the bamboo, the coco-tree, the ground-nut, the yam, the cassava, and others besides, are of practical importance. The cultivation of sugar and coffee owes its development to the Dutch; and to them also is due the success of nearly all the other crops they have greatly encouraged the cultivation of the coco-nut among the natives, and it flourishes, especially in the coast districts, in almost every island in their territory. The oil is largely employed in native cookery. Pepper, nutmegs, cloves were long the objects of the most important branch of Dutch commerce; and in the markets of Dutch and Chinese the benzoin and other forest products have a place among the exports.

To the naturalist the Malay Archipelago is a region of the highest interest; and from an early period it has attracted the attention of explorers. Of the many Archipelago, and the Asie, and Asiatic and Australian regions is clearly reflected in the botany and zoology. The flora of the Asiatic islands (thus distinguished) is sparingly developed in that region, and the flora of the islands (the flora intermingles with that of Australia) (E. H. H. Guilmard, Australasia). Similarly, in the Asiatic islands are found the great mammals of the continent—the elephant, tiger, rhinoceros,
anthropoid ape, &c., which are wanting in the Australian region, with which the eastern part of the archipelago is associated. (For details concerning flora and fauna, see separate articles, especially Java.)

Inhabitants.—The majority of the native inhabitants of the Malay Archipelago belong to two races, the Malays and the Melanesians (Papuans). As regards the present racial distribution, the view accepted by many anthropologists, following A. H. Keane, is that the Negritos, still found in the Philippines, are the true aborigines of Indo-China and western Malaysia, while the Malays are related to the Polynesians and inhabitants of eastern Malaysia and western Polynesia. At some date long anterior to history it is supposed that Indo-China was occupied first by a fair Caucasian people and later by a yellow Mongol race. From these two have come all the peoples—other than Negrito or Papuan—found to-day from the Malay Peninsula to the farthest islands of Polynesia. The Malay Archipelago was thus first invaded by the Caucasians, who eventually pushed eastward and are to-day represented in the Malay Archipelago only by the Mentawi islanders. They were followed by an immigration of Mongol-Caucasian peoples with a preponderance of Caucasian blood—the Indonesians of some, the pre-Malays of other writers—who are to-day represented in the archipelago by such peoples as the Dyaks of Borneo and the Bettas of Sumatra. At a far later date, probably about the 1st century of the Christian era, the Chinese reached the islands, and in many cases, and especially in Borneo, the Chinese were assisted by the Malays in the establishment of a number of bases, which, however, were in no case more than the native tongue of the Javanese, and it is spoken by a greater number of people than any of the others. To it Sundanese stands in the relation that Low German holds to High German, and the Madurese in the relation of a strongly individualized dialect. Among the other languages which have been reduced to writing and grammatically analyzed are the Balinese, closely connected with the Javanese, the Bata (with its dialect the Toba), the Dyak and the Macassarese. All these, a vague term meaning in the mouths of the natives little else than non-Mahomedan, has been more particularly applied by Dutch philologists to the native speech of certain tribes in Celebes. The commercial activity of the Buginese causes their language to be fairly widely spoken—little, however, by Europeans.

Political Division.—Politically the whole of the archipelago, except British North Borneo, &c. (see Borneo), part of Timor (Portuguese), New Guinea east of the 141st meridian (British and German), and the Philippine Islands, belongs to the Netherlands; the Philippine Islands which had been for several centuries a Spanish possession passed in 1898 by conquest to the United States of America. For the political division of the political units see the separate articles; a general view, however, is here given of the government, economic conditions, &c., of the Dutch possessions, which the Dutch call Nederlandsch-Indie.

Netherlands Indies

Administration.—The Dutch possessions in Asia lie between 6° N. and 11° S. and 95° E. and 141° E. Politically they are divided into lands under the direct government of the Netherlands and confederated lands. Administratively they are further divided into residencies, divisions, regencies, districts, and districts or villages. In the principal towns and villages there are parish councils, and in some provinces county councils have been established. Natives, Chinese and Arabs, are given seats, and in certain instances some of the members are elected, but more generally they are appointed by government. The islands are often described as of two groups, Java and Madura forming one, and the other consisting of Sumatra, Borneo, Timor, Lingga Archipelago, Banka, Billiton, Celebes, Molucca Archipelago, and the Moluccas, and a part of New Guinea—the Outposts as they are collectively named. The Outposts are divided into 20 provinces. A governor-general holds the supreme administrative and executive authority, and is assisted by a council of ministers. Each province has a government, which is also divided into a legislative and an executive branch, the former being represented by the council, the latter by the governor and his council. Each has also its own legislature. Each of the provinces has its own army and navy, which are composed of local residents. The islands are divided into 146 districts, each with its own governor. The administration of the larger islands (Java and Madura) is under the control of the governor-general of Java and the Netherlands East Indies. The general administration of the islands of the Netherlands East Indies is under the supervision of the government of the Netherlands Indies. The administration of the smaller islands (the Outposts) is under the control of the governor of the Outposts. The government of the Netherlands Indies is responsible to the Dutch Diet. The government of the Outposts is responsible to the government of the Netherlands Indies. The government of the Netherlands Indies is responsible to the Dutch Diet.

The following table gives the area and population of Java (including Madura) and of the Outposts:

In no case are the figures for population more than fairly accurate, and in some instances they are purely conjectural. The population is legally divided into Europeans and persons assimilated to them, and natives and persons assimilated to them. The first class includes all half-castes, persons of mixed blood, and all Dutch subjects in closer relationship with the natives than is the case with most colonizing peoples, and also Armenians, Jews, &c., and the total number of this class in 1900 was 75,833. Of 12,007 of these were born in Java, 3,137 in Borneo, 2,507 in Sumatra, 2,007 in Celebes, and 626 in Java in 1898. Of the total number of this class in 1900 there were also 1,982 Chinese, 1,567 Hindoos, 1,382 Japanese, 1,382 Germans, 1,382 British, and 1,382 Belgians. Among the natives and persons assimilated to them were about 537,000 Chinese and 27,000 Arabs. In the decade 1890-1900 the increase was 14% of the population, of which 30% was Chinese and 16% of the Chinese of 16-50 years. A large proportion of the Europeans are government officials, or retired officials, for many of the Dutch, once established in the colonies, settle there for life. The remaining Europeans are mostly planters and heads of industrial establishment.

1 Including 487 in Merauke, the capital of Dutch New Guinea.
ments; the Arabs are nearly all traders, as are some of the Chinese, but a large number of the latter are labourers in the Sumatra tobacco plantations and the tin mines of Banka, Billiton, &c. The bulk of the natives are agriculturists.

Religion and Instruction.—Entire liberty is granted to the members of all religious confessions. The Reformed Church has about 40 ministers and 30 assistants, the Roman Catholic 35 curates and 20 priests, not salaried out of the public funds. There are about 170 Christian missionaries, and in progress their work may be illustrated by showing that the number of Christians among the natives and foreign Orientals was:

About 10,000 natives go annually to Mecca on pilgrimage.

Both the government and private enterprise maintain vernacular schools. Large sums have been voted in Holland for the establishment of primary and secondary schools, and the government has undertaken to assist in the establishment of parochial schools, the object being that every village, at least in Java, shall have a school. There are schools for higher education at Batavia, Surabaya and Semarang; at the first of these two towns are government schools for mechanical engineering, and at Batavia a crafts school and a medical school for natives. There are five colleges for native students—secondary and four for sons of native officials. Government schools for the education of Chinese children are established in the principal towns. Private mechanical and crafts schools are established at Jokjakarta, Surabaya and Semarang, and there is an agricultural school at Jentenzeg.

Justice.—As regards the administration of justice, the distinction is maintained between (1) Europeans and persons assimilated with them (who include Christians and Japanese), and (2) natives, together with Chinese, Arabs, &c. The former are subject to laws closely resembling those of the mother country, while the customs and institutions of natives are respected in connexion with the administration of justice to the latter. In 1906 a bill was passed simplifying the existing system of the courts, by abolishing the distinction, and especially directing new ordinances with regard to the judicial treatment of Christian natives. A general judicial revision being also in contemplation, this bill did not immediately come into force, but was administered by European judges, but, as with administration at large so in judicial matters, native chiefs have extensive powers in native affairs. For European justice the High Court of Justice is established at Batavia; there are also courts of justice in both Java, Sumatra, and Bencoolen, with authority not only over Java but over parts of the Outposts; there is a resident court of justice in each residency. For native justice there are courts in the districts and regencies; residents act as police judges; provincial councils have judicial powers, and there are councils of priests with powers in matrimonial disputes, questions of succession, &c.

As regards pauperism, the government subsidizes Protestant and Catholic orphanages.

Finance.—The revenue of Netherlands India has been derived mainly from customs, excise, ground-tax, licences, poll-tax, &c., from monopolies—opium, salt and pawn-shops (the management of which began to be taken over by the government in 1903, in place of the previous system of farthing-out), coffee, &c., railways, tin mines and forests, and from agricultural and other concessions. But attempts have been made, and have been largely successful, to make the revenue dependent to a less extent on monopolies and the collection of duties on the land, and to abolish licences and substitute direct taxes. There is a progressive income tax, for Europeans, and the system has also been applied in the case of natives.

The following table affords comparisons in the revenue and expenditure:

The monetary system is similar to that of Holland (the unit being the guider), but there are also certain silver and copper coins of small value bearing Malay or Javanese inscriptions. In the Java Bank, established in 1828, with headquarters at Batavia, is the only bank issuing notes, two-thirds of the amount which must be covered by specie or bullion. The government has a control over the administration of this bank.

Defence.—The army is purely colonial, i.e., distinct from that of the Dutch Netherlands. Its strength is a little over 40,000, about one-third being Europeans of various nationalities and two-thirds natives of various races. No portion of the regular army of the Netherlands is allowed to be sent on colonial service, but individual soldiers are at liberty to enlist, by permission of their commanding officers, in the army of Netherlands India, and they form its nucleus. Native and European soldiers are generally mixed together in the same regiments. The number of all Dutch till 1908, when a trial was made of native officers from noble Javanese families. The artillery is composed of European gunners, with native riders, while the cavalry are Europeans and natives. A military academy is established at Meester Cornelis, near Batavia, for colonial soldiers. There are certain local forces outside the regular army—militia in some of the large towns, native infantry in Madura, and guards of some of the vassal princes. Unlike the army, which is purely colonial, in native infantry Netherlands India is partly, and belonging to the royal navy of the Netherlands, and its expenses are therefore borne partly by the mother country and partly by the colony. About six ironclads and twenty smaller vessels of the royal navy are stationed in colonial waters; the vessels of the colonial marine number about twenty-four, and undertake police supervision, prevention of slave trading, &c.

Trade and Industries.—The principal articles of export are sugar, tobacco, rice, coffee, lauff, tea, cinchona, tin, rice, pepper, spices and ganier. The average annual value of exports during 1900–1905 was £2,496,408, and of imports £1,709,338. A great proportion of the exports goes to the United States, while the leading European countries—Germany, France, England, and Spain—spend comparatively very little. The export of rice to China is stopped by an order of the Imperial government, and the rice is mainly consumed at home or sent to the colonies. The export of rice to China is stopped by an order of the Imperial government, and the rice is mainly consumed at home or sent to the colonies. The export of rice to China is stopped by an order of the Imperial government, and the rice is mainly consumed at home or sent to the colonies. The export of rice to China is stopped by an order of the Imperial government, and the rice is mainly consumed at home or sent to the colonies. The export of rice to China is stopped by an order of the Imperial government, and the rice is mainly consumed at home or sent to the colonies.

There are 13,195 miles of railways and 1,077,995 miles of canals in the Netherlands. The total annual yield of the tin mines is about 15,000,000 tons, and the coal mines 240,000,000 tons. The average annual output of petroleum in the Netherlands is 120,000,000 tons, while the average number of vessels engaged in the trade is about 400,000. The average annual output of petroleum is 120,000,000 tons, while the average number of vessels engaged in the trade is about 400,000. The average annual output of petroleum is 120,000,000 tons, while the average number of vessels engaged in the trade is about 400,000. The average annual output of petroleum is 120,000,000 tons, while the average number of vessels engaged in the trade is about 400,000.

**MALAY ARCHIPELAGO**

**History**

Portuguese and Spanish Ascendancy, 1511–1595—Ptolemy and other ancient geographers describe the Malay Archipelago, or part of it, in vague and inaccurate terms, and the traditions they preserved were supplemented in the middle ages by the travels of a few famous travellers, such as Ibn Batuta, Marco Polo, Odoric of Pordenone and Niccolò Conti. Malay and Chinese records also furnish material for the early history of individual islands, but the known history of the archipelago as a whole begins in the 16th century. At this period a civilization, largely of Hindu origin, had flourished and decayed in Java, where, as in all the more important islands, Mahomedanism had afterwards become the dominant creed. But the smaller islands and the remoter districts, even of Java and Sumatra, remained in a condition of complete savagery.

The Portuguese were the first Europeans to colonize any part of the archipelago. A Portuguese squadron under Diogo Lopes de Sequeira arrived off Sumatra in 1500, explored the north coast for some distance, and noted that the inhabitants of the interior were cannibals, while those of the littoral were civilized and possessed a gold coinage. The main object of the Portuguese was to obtain a share in the lucrative spice trade carried on by the Malays, Chinese and Japanese; the trade-routes of the archipelago converged upon Malacca, which was the principal centre for spice merchants trading with every country on the shores of the Indian Ocean and Arabian Sea. In 1511 the Portuguese under Alphonso d’Albuquerque occupied Malacca, and in November of that year an expedition under Antonio de Abreu was despatched to find a route to the Moluccas and Banda Islands, then famous for their cloves and nutmegs. The explorers reached Amboyna and Ternate, after gaining some knowledge of Java, Madura, Sumbawa and other islands, possibly including New Guinea. During the return voyage the second-in-command, Francisco Serrão, was shipwrecked, but succeeded in making his way in a native boat to Mindaño. Thus the Philippines were discovered: In 1514 a second Portuguese fleet arrived at Ternate, which during the next five years became the centre of Portuguese enterprise in the archipelago; regular traffic with Malacca and Cochín was established, and the native raja became a vassal of Portugal.

Meanwhile the Spanish government was considering whether the Moluccas did not fall within the Spanish sphere of influence as defined by the Treaty of Tordesillas in 1494; and in August, 1519 an expedition commanded by Ferdinand Magellan (q.v.) sailed from Seville to seek a westward passage to the archipelago. After losing the commander in the Philippines and discovering Borneo, the two surviving ships reached the Moluccas late in 1520. One vessel returned to Seville by the Cape route, thus completing the first voyage round the world; the other attempted to return by the Pacific, but was driven back to Tidore and there welcomed by the natives as a useful ally against the Portuguese. Reinforcements from Spain arrived in 1525 and 1528; but in 1529 a treaty was concluded between the emperor Charles V. and John III. of Portugal, by which, in return for 350,000 gold ducats, the Spanish claim to the Moluccas was withdrawn. The boundary between the Spanish and Portuguese spheres was fixed at 17° E. of the Moluccas, but by a geographical fiction the Philippines were included within the Spanish sphere. Further disputes occurred from time to time, and in 1542 a Spanish fleet came into conflict with the Portuguese off Amboyna; but after 1530 the supremacy of each power in its own sphere was never seriously endangered.

Though the Portuguese traders frequented the coast of Java, they annexed no territory either there or in Sumatra; but farther east they founded numerous forts and factories, notably in Amboyna, the Banda Island, Celebes and Halmahera. Ternate remained the seat of the governor of the Moluccas, who was the highest official in the archipelago, though subordinate to the vice-roy or governor of Portuguese India. The first attempt to enter into relations with the states of Borneo was made by D. Jorge de Menezes, who visited Brunci in 1526, and in 1528 sent an envoy to its raja. The embassy failed in a curious manner. Among the gifts sent by Menezes was a piece of tapestry representing the marriage of Catherine of Aragon to Arthur, prince of Wales. The raja was persuaded that these mysterious figures were demons under a spell, which might come to life and kill him as he slept. The envoy was therefore dismissed.

In 1536, after a period of war and anarchy caused by the tyrannical rule of Menezes, Antonio Galvão, the historian, was appointed governor of the Moluccas. He crushed the rebellion and won the affection of the natives by his just and enlightened administration, which had no parallel in the annals of Portuguese rule in the archipelago. He returned to Europe in 1540 (see Portugal: Literature), after inaugurating an active missionary movement, which was revived in 1546–1547 by Francis Xavier (q.v.). At this period the Portuguese power in the East was already beginning to wane; in the archipelago it was weakened by administrative corruption and by incessant war with native states, notably Bintang and Achin; bitter hostility was aroused by the attempts which the Portuguese made to establish a commercial monopoly and to force Christianity upon their native subjects and allies (see Portugal: History). From 1580 to 1640 Dutch and English were in control of the East—a union which differed from annexation in little but name.

The English and Dutch, 1595–1674.—Pirates from Dieppe visited the archipelago between 1527 and 1539. It is possible that they reached Australia1—more than sixty years before the first voyage thither of which there is any clear record; but their cruise had no political significance, and the Spaniards and Portuguese remained without European competitors until the appearance of Sir Francis Drake in 1579. An English squadron under Sir James Lancaster came into conflict with the Portuguese in 1591, and an expedition under Sir Henry Middleton traded in the archipelago in 1604. But the English were simple traders or explorers; far more formidable were the Dutch, who came to the East partly to avenge the injuries inflicted on their country by the Spaniards, partly to break the commercial monopoly of the peninsular states. As middlemen they already possessed a large interest in the spice trade, for the Portuguese, having no direct access to the principal European markets, had made a practice of sending cargoes to the Netherlands for distribution by way of the Scheldt and Rhine. The Dutch now sought to monopolize not only the distribution but the production of spices—an enterprise facilitated by the co-operation of many exiled Portuguese Jews who had settled in Holland.

The first Dutch fleet sailed from Texel, under the command of Cornelis Houtman, on the 2nd of April 1595 and reached Sumatra on the 1st of January 1596. It visited Madura, and came into conflict with the Portuguese at Bantam in Java, returning to Holland in 1597. Though not a commercial success, the expedition had demonstrated the weakness of the Portuguese. In 1602 the Dutch East India Company (q.v.) was incorporated, and for nearly two centuries this organization played the chief part in the history of the archipelago. By 1604 the Dutch could already claim to be the stronger power at sea. They had attacked the Portuguese in Ceylon (1601), established friendly relations with Achin (1602), and defeated a powerful fleet off Banda (1603). In 1606 they concluded a treaty of alliance with the sultan of Johor, and in 1608 they forced the Portuguese to aspire to an armistice for twelve years. On the 26th of November 1609 Pieter Both was chosen by the states-general, on the nomination of the Dutch East India Company, as first governor-general of Netherlands India. In 1611 the headquarters of the Dutch was changed from Bantam to Jakarta, which in 1619 was renamed Batavia, and was thenceforward the Dutch capital. Meanwhile the English East India Company, chartered in 1600, had also extended its operations to the archipelago. After 1611 the commercial rivalry between the Dutch and British became acute, and in 1613, 1615 and 1618 commissioners met in London to discuss the matters in dispute. The result of their deliberations was the Treaty of Defence, signed on the 2nd of June 1616 and modified on the 24th of January 1626, which arranged for co-operation between the Dutch and British companies, and especially for the maintenance

---

1 See The Geographical Journal, ix. 80 seq. (London, 1897).
of a joint fleet. But neither company could restrain its agents in the East from aggressive action, and many fresh causes of dispute arose, the chief being the failure of the British to provide the naval forces required for service against the Portuguese, and the so-called “massacre of Amboyna” (q.v.) in 1623. The Treaty of Defence lapsed in 1637, but as early as 1634 the British made peace with Portugal. Even without allies, however, the Dutch continued to extend their trade and to annex fresh territory, for the British were weakened by civil war at home, while, after 1640, the Portuguese were struggling to maintain their independence against Spain. The Dutch company opened up a profitable trade with Japan and China, and prosecuted the war against Portugal with great vigour, invading Portuguese India and capturing Point de Galle in 1640, Malacca in 1641, Cochin and Cannanore in 1663. The war with England in 1652-54 and the renewal of the Anglo-Portuguese alliance by the marriage of Charles II to Catherine of Braganza in 1661 were unable to check the growth of Dutch power. The bounds of the resistance offered by some of the native states. Rebellions in Java (1620) and the Moluccas (1650) were suppressed with great severity, but in 1662 the company suffered a heavy reverse in Formosa, all its colonies being expelled from the island. A new war between Great Britain and Holland broke out in 1672 and was terminated by the Treaty of Westminster (February 17, 1674), by which the points at issue between the two companies were referred first to commissioners and finally to an arbitrator. The full details of the settlement are unknown, but thenceforward the British company devoted its energies chiefly to the development of its Indian possessions, while the Dutch were left supreme in the archipelago. In 1684 the British even evacuated Bantam, their chief settlement, and retired to Benkulen in Sumatra, which remained for more than a century their sole territorial possession in the archipelago.

Dutch Ascendancy, 1674-1749.—The weakness of Spain and Portugal and the withdrawal of the British left the Dutch company free to develop its vast colonial and commercial interests. In 1637 the so-called Dutch “colonial system” had been inaugurated by the fourth governor-general, Jan Pieterszoon Coen (q.v.). Under this system, which was intended to provide Netherlands India with a fixed population of European descent, Dutch girls were sent to the archipelago to be married to white settlers, and subsequently marriages between Dutchmen and captive native women were encouraged. As early as 1624 vast fortunes had been acquired by trade: two members of the company who died in that year were stated to possess seven and eight tons of gold respectively, an amount approximately equivalent, in the aggregate, to £2,000,000. The use of slave labour, and the application of the corvée system to natives who were nominally free, enabled the company to lower the cost of production, while the absence of competition enabled it to raise prices. The hardship inflicted on the native races provoked an insurrection throughout Java, in which the Chinese settlers participated; but the Dutch maintained naval and military forces strong enough to crush all resistance, and a treaty between the company and the Susuhunan in November 1749 made them practically supreme throughout the island.

Decline of Dutch Power, 1749-1811.—In the second half of the 17th century the monopoly system and the employment of slaves and forced labour gave rise to many abuses, and there was a rapid decline in the revenue from sugar, coffee and opium, while the competition of the British East India Company, which now exported spices, indigo, &c. from India to Europe, was severely felt. The administration was corrupt, largely because of the vast powers given to officials, who were invariably underpaid; and the financial methods of the company precipitated its ruin, large dividends being paid out of borrowed money. The burden of defence could no longer be sustained; piracy and smuggling became so common that the company was compelled to appeal to the states-general for aid. In 1708 it was abolished and its authority vested in a “Council of the Asiatic Possessions.” In 1803 a commission met to consider the state of the Dutch colonies, and advocated drastic administrative and commercial reforms, notably freedom of trade in all commodities except firearms, opium, rice and wood—with coffee, pepper and spices, which were state monopolies. Some of these reforms were carried out by H. W. Daendels (1808-1811), who was sent out as governor-general by Louis Bonaparte, after the French conquest of Holland. Daendels, however, maintained the existing restrictions upon trade and even made rice a state monopoly. His harsh rule aroused great antagonism; in 1811 he was recalled and J. W. Janssens became governor-general.

British Occupation, 1811-1816.—Netherlands India was at this time regarded as a part of the Napoleonic Empire, with which Great Britain was at war. A British naval squadron arrived in the Moluccas in February 1810 and captured Amboyna, Banda, Ternate and other islands. In 1811 a strong fleet was equipped by Lord Minto, then governor-general of India, for the conquest of Java; a British force was landed on the 4th of August; Batavia was captured on the 26th, and on the 8th of September Janssens and the remnant of his army surrendered. Lord Minto had issued a proclamation establishing British rule on the 11th of September, and Thomas (afterwards Sir Thomas) Stamford Raffles was appointed lieutenant-governor. Raffles (q.v.) held office until March 1816, and introduced many important changes in the departments of revenue, commerce and judicature. He was succeeded by John Fendall, who in 1816 carried out the retrocession of Netherlands India to the Dutch, in accordance with the Treaty of Vienna (1814).

Restoration and Reform of Dutch Power, 1816-1910.—Various disputes between Great Britain and the Netherlands, arising chiefly out of the transfer of power in Java and the British occupation of Singapore (1819), were settled by treaty between the two powers in 1824. By this treaty the Dutch were given almost entire freedom of action in Sumatra, while the Malay Peninsula was recognized as within the British sphere of influence. In 1825-30 a serious rebellion in Java involved the despatch of a large military force from the Netherlands, and was with difficulty suppressed. An outbreak of Mahomedan fanaticism in Sumatra also gave much trouble.

The reform movement inaugurated by the commission of 1803 was resumed in 1830, when Governor-General Johannes van den Bosch endeavoured to improve the conditions of land-tenure and agriculture by introducing the so-called “culture system.” The native cultivators were to be exempted from the ground-tax, but were to cultivate one-fifth of their land as the government might direct, the government taking the produce. This culture-system worked fairly during Van den Bosch’s tenure of office, but gave rise to many abuses between 1833 and 1844, involving, as it did, a combination of the métayer and corvé systems.

In 1848 the Grondwet, or fundamental law of the Netherlands, recognized for the first time the responsibility of the Dutch nation for its colonial dependencies. The Grondwet involved certain important changes, which were embodied in an act passed in 1854 and commonly known as the Regulations for the Government of Netherlands India. The Regulations substituted statute law for administrative and military despotism, and made the governor-general in council responsible to the minister of the colonies at the Hague. They reformed the judicature, introduced elementary education for the natives, and abolished slavery in Java as from the 1st of January 1860. They also prepared the way for further legislation tending towards the gradual emancipation of the natives from the culture system, and from semi-feudal servitude to their native rulers. That servitude existed in many forms all over the archipelago, but among the most curious must be reckoned the pandelingschap or “pledgedom,” which originated in Borneo, and according to which a man had the power to make his debtor his serf for life.

The reform movement was aided by the publication in 1860 of Max Havelaar, a romance by E. Douwes Dekker (q.v.), which contained a scathing indictment of the colonial system. Many important financial and agrarian measures were carried between 1860 and 1890. In 1863 Fransen van de Putte, minister for the colonies, introduced the first of the annual colonial budgets for
which the Regulations had provided, thus enabling the states-
general to control the revenue and expenditure of Netherlands
India; in 1865 he reduced and in 1872 abolished the differen-
tiation of customs dues in favour of goods imported from Holland,
substituting a uniform import duty of 6% and establishing a
number of free ports throughout the archipelago. The import
duty was considered so moderate that an increase required for
revenue purposes was readily conceded in 1886. In 1876 the
practice of paying a yearly surplus (batik slot) from the revenues
of Netherlands India to the treasury at the Hague was
discontinued. The chief reforms in the land system were those intro-
duced by De Waal, then minister for the colonies, in 1879. The
cultivation of pepper, cochineal, cinnamon and indigo for the
government had already ceased; De Waal restricted the area of the
sugar plantations (carried on by forced native labour) as
from 1878, and provided for their abolition after 1890. He also
enacted natives to secure proprietary rights over the land they
cultivated, and legalized the leasing of Crown-forest-lands to
Europeans.

The extension of Dutch political power—notably in Java,
Sumatra, Celebes, the Moluccas, Borneo, the Sundas Islands and
New Guinea—proceeded simultaneously with the reform move-
ment, and from time to time involved war with various native
states. A large expedition was sent to Lombok in 1894, and
almost the whole of that island was incorporated in the Dutch
dominions. The long and costly war with Achin (q.v.) began in
1873 and reached its climax in the military occupation of the
country after 1895, when the native sultan surrendered and was
deporated. A guerrilla war was still carried on by his subjects, but
their principal leader, the chief Panglima Polim, was captured in
1907; in 1908-1910 the condition of Achin under the military rule
of General Swart was one of almost unbroken peace, and taxes
were regularly paid.

While the Dutch were thus consolidating their authority, other
countries were acquiring new commercial or colonial interests in
the archipelago. Immigration from China and Japan steadily
increased, especially towards the end of the period 1816-1910.
The enterprise of Sir James Brooke (q.v.) led, after 1838, to the
establishment of British sovereignty in North Borneo; in 1895
New Guinea was divided between Great Britain, Germany and
the Netherlands; and the Spanish-American War of 1898 resulted
in the cession of the Philippines, Sulur Island and the largest of
the Mariana Islands to the United States, and the sale of the Caroline
group to Germany. Australian and Japanese trade in the archi-
pelago was stimulated by the establishment of the Australian
Commonwealth (1901) and the Russo-Japanese War (1904-5).
In 1910 the nations most directly interested in the future of the
archipelago were the Netherlands, Great Britain, the United
States, Germany, Japan, China and Portugal.

BIBLIOGRAPHY.—For the period 1511-1835, the chief Portuguese
authorities are the chronicles of Barros, Corêa, Caetanheda and
Couro (see PORTUGAL: History), with the letters of Xavier (q.v.),
and the Tratado de A. Galvão (Lisbon, 1565 and 1731), of which a
translation entitled Discoveries of the World was made for Richard
Hakluyt and published by the Hakluyt Society, London, 1862;
See also: J. A. de Pina, A. C. de Sá, O. A. de Carvalho, F. de Navarette, Colección de los viajes (vol. 4 and 5,
Madrid, 1837). For later history see John Crawford, History of the
Indian Archipelago (Edinburgh, 1829), which quotes from native
as well as European records, and Twentieth-Century Impressions of
Netherlands-Indies (London, 1929). Where works are of linguistic
interest, they give references to the principal English and Dutch authorities. Further
bibliography will be found in J. A. van der Chis, Proeve eener neder-
landsch-indische Bibliografie, 1659-1870 (Batavia, 1875).

MALAY—MALAY PENINSULA

MALAYIR, a small province of Persia, situated between
Hamadan and Burjird. It possesses about 70,000
and, together with the district Tusirkhan, pays a yearly revenue of
about £13,000. It produces much corn and fruit; a great
quantity of the latter, dried, is exported. Its capital and seat of
government is Dolatabad (Dowlatabad), a thriving little city, with
a population of about 5000, situated at an elevation of 5680 ft.,
38 m. from Hamadan and 32 m. from Burjird. It has post and
telegraph offices.

MALAY PENINSULA (called by the Malays Tanah Malaya, i.e. the Malay Land), a lozenge-shaped strip of land projecting
into the China Sea, and forming the most southerly portion of the
continents of Asia. Geographically, the peninsula begins at the
isthmus of Kra, at N, which project on either side by a width of
70 m. in width, and the distance from sea to sea is further
diminished by a large irregular salt-water inlet. Politically and
anthropologically, however, this upper portion must be regarded as
a continuation of the kingdom of Siam rather than as a section of
Malaya. From the isthmus of Kra the peninsula extends
south with a general inclination towards the east, the most
southerly point being Tanjong Bulus in r° 16½'. A line drawn
diagonally down the centre from the isthmus of Kra to Cape
Romanya (Ramunya) gives the extreme length at about 750 miles.
The breadth at the widest point, from Tanjong Pen-unjut in
Trengganu to Tanjong Hantu in the Dindings territory, is about
200 m. The area is estimated at about 70,000 sq. m. The peninsula
is bounded on the N. by Siam, on the S. by the island and strait of Singapore, on the E. by the China Sea, and on
the W. by the Strait of Malacca.

Physical Characteristics.—A range of granite mountains forms a
 backbone to the peninsula, and projects either directly to
the sea or is walled in by the country of the Sulu archipelago to
the west. The highest peak is the Mount Besut, 11,383 ft.,
which is situated on the east coast of the Malay Peninsula
where the latter borders Malaya. A continuation of the mountains
of Java, this range is composed mainly of granite and obsidian;
the rocks are covered with a mantle of debris which has
been superimposed upon the granites. The highest known peak in
the main range is that of Gunung Korbu, 7217 ft. above sea-level.
The highest mountain is believed to be Gunung Tahan, which
forms part of the eastern range of isolated mountains in the
coastlands of Selangor and Kelantan, and is estimated at about 8000 ft. The west coast
throughout its whole length is covered to a depth of some miles
with mangrove swamps, with only a few isolated stretches of sandy
coastland. The valley bottoms are generally flat and
are covered by limestone which has been

K.G. J.
finest on the west coast, while those of Chudu and Koto Glangi in Pahang are the most extensive yet visited by Europeans on the east coast. They are all of limestone formation. So far as is known, the Malay Peninsula consists of an axial zone of crystalline rocks, flanked on the east by a series of Carboniferous and Triassic deposits and on the west by a belt of sedimentary rocks. Granite is the most widely spread of the crystalline rocks; but dikes of various kinds occur, and gneiss, schist and marble are also met with. These rocks form the greater part of the central range, and many of the smaller ranges and islands are composed of them to a considerable depth. The sedimentary deposits include slate, limestone, and sandstone. Impure coal has also been recorded. The limestone has yielded *Proetus, Chionites* and other fossils, and is is very rich in shells. The Triassic deposits have yielded *lotong*, *russel*, *jak*, and *nau-nau*. The Triassic and other Triassic fossils have been found, and it appears to belong to the Khaotic or Upper Trias. The minerals produced are tin, gold, iron, galena and others, in insignificant quantities.

The tin occurs in the form of cassiterite, and is found chiefly in or near the crystalline rocks, especially the granite. As stream tin it occurs abundantly in some of the alluvial deposits derived from the crystalline area, especially on the east coast. Only two tin lodes have been worked, that at Kluang, the last shaft, the shafts at the one at Kuantan in Pahang, the other at Bandel in Trengganu territory. On the west coast no true lode has yet been discovered, though the vast alluvial deposits of tin found there seem to make such a vein probable in the future. Since 1905, it is usually produced from these alluvial beds has supplied between 50% and 75% of the tin of the world. Gold is worked with success in Pahang, and has been exploited from time immemorial by the natives. The deposits of gold are small quantities have also been found on the western slope in Perak.

**Climate, &c.**—It was formerly the custom to speak of the Malay Peninsula as an unhealthy climate, and even to compare it with the western coast of Africa. This, however, that, though hot, it compares favourably with that of Burma. The complaint which Europeans make concerning it is the extreme humidity, which causes the heat to be more oppressive than in the case where the air is dry. On the other hand, the thermometer, even at Siak, not the most unhealthy place, which is considerably lower than the mean for the year at that place is generally below 80°. On the mainland, and more especially on the eastern slope, the temperature is considerably lower. The average number of rainy days throughout the peninsula varies from 200 to 300 per year, and the average number of rainy days is about 155 in per annum. Malarial fevers make their appearance in places where the forest has been recently felled, or where the surface earth has been disturbed. It is noticed that labourers employed in deforestation suffer from fever attacks and yellow fever. The soil is too warm, and the forest is too short, for the mosquitoes. To Europeans the climate is found to be relaxing and enravishing, but if, in spite of some disinclination for exertion, regular exercise is taken from the beginning, and ordinary precautions against chills, more especially from that Cosmos and grass are situated, the cold is good as a chance of remaining in good health in the peninsula as in Europe. A change of climate, however, is imperatively necessary every five or six years, and the children of European parents should not be kept in the peninsula after they have stayed there for four or five years. The Chinese immigrants suffer chiefly from fever of a malarial type, from beri-beri, a species of tropical dropsy, and from dysentery. The Malays formerly suffered severely from smallpox, but since the introduction of the Jennerian Vaccination on rule vaccination has been introduced, and the ravages of the disease no longer assume serious dimensions. Occasional outbreaks of cholera occur from time to time, and in the independent states these cause terrible loss of life, as the natives fly from the disease and spread the infection in every direction. As a whole, the Malays are, however, a remarkably healthy people, and deformity and hereditary diseases are rare among them. There is little leprosy in the peninsula. The fly is not abundant, but it makes its way near Penang on Pulau Deraja and another on an island on the west coast, recent from the Federated Malay States.

**Flora and Fauna.**—The soil of the peninsula is remarkably fertile but the climate is unhealthy. In the west forests is the decay of vegetable matter during the hot season, and it is filled up by the forest fires. The soil to the depth of many feet, and from it springs the most marvellous tangle of huge trees, shrubs, bushes, underwood, creepers, climbing plants and trailing vines, the whole hung with ferns, mosses, and parasitic growths, and bound together by rattans and huge vines. Such is the covering of the forest that it is impossible to force a way through it without the aid of a woodknife, and even the wild beasts use well-worn game-tracks through the forest. In the interior of bamboo are found, many of which are spiny, and the big bears, wild pigs, and deer are usually able to force a way. On the coast, the mangrove or *Impressa* is found with other mangroves and a variety of small plants and trees, and the localities are rich in cork, and rubber of several varieties, and kinds of rattan. The mangrove grows on the shores of the west coast in profusion. Aglae-wood, the camphor tree, and ebony are also found in smaller quantities.

The fauna of the peninsula is varied and no less profuse than the vegetable life. The Asiatic elephant: the *elephas*, a bison of a larger type than the Indian gaur: two varieties of rhinoceros: the honey bear (jon). The tapir, the sambar (rsu), the speckled deer (kijang), three varieties of mouse-deer (nopoh, plakod and kanchil); the giraffe (*unguca* or *wosu*), the sambar, another species of antelope, the brook (croco-nut monkey), so called because it belongs to the species of *Crotalus*, the *pristis* (kay), the reticulated python, the short-tailed pipistrelle, the flying fox; the python, the cobra, and many other varieties of snake, including the hamadryas, the alligator, the otter and the gavial, as well as thousand kinds of squids, rat, &c., are found on the coast. The jungles are filled with insects of all kinds, from to beautiful butterflies, and from sticks to leeches, insects of all kinds.

The study of the insect life of the peninsula opens a splendid field for scientific research, and the profusion and variety of insects found in these forests probably surpass those to be met with anywhere else in the world.

**Political Divisions and Population.**—Politically the Malay Peninsula is divided into four sections: the colony of the Straits Settlements and the Federated Malay States; the independent Malay State of Johor, which is within the British sphere of influence; the non-federated states under British protection; and the groups of states to the north of Perak and Pahang which are not recognized as lying within the sphere of influence of Siam. The colony of the Straits Settlements consists of the islands of Singapore, Penang and the Dindings, the territory of Province Wellesley, on the mainland opposite to Penang, the insidious territory of the Dindings, and the town and territory of Malacca. The Federated Malay States under British protection consist of the sultanates of Perak, Selangor and the Negri Sambilan on the west coast, and the sultanate of Pahang on the east coast. Johor is the only Malay state in the southern portion of the peninsula, the whole of which is within the British sphere, which has been suffered to remain under native rule. The non-federated states under British protection (since 1909) are Kelantan, Trengganu, Kedah and Perak (Palt). The population of the peninsula numbers about 2,000,000, of whom about 600,000 inhabit the colony of the Straits Settlements, about 600,000 the Federated Malay States, about 200,000 the Malay State of Johor, and about 250,000 to 300,000 the remainder of the peninsula. The population of the peninsula includes about 85,000 Chinese, mostly immigrants or descendants of immigrants from the southern regions of China; and about 30,000 Europeans. The colony of the Straits Settlements, 350,000 in the Federated Malay States, 150,000 in Johor, and the remainder in smaller communities or as isolated traders scattered throughout the villages and small towns of the peninsula. The Malay Peninsula, including immigrants from the eastern archipelago, number

---

some 750,000 to 800,000, while the Tamils and other natives of India number about 100,000, the aboriginal natives of the peninsula perhaps 20,000, Europeans and Americans about 6500, and Eurasians about 9000. The colony of the Straits Settlements, and to a lesser extent the towns of the Federated Malay States, carry a considerable heterogenous population, in which most of the races of Asia find their representatives.

Races of the Peninsula.—Excluding the Tai, or Siamese, who are undoubtedly recent intruders from the north, there are three races which for an extended period of time have had their home in the Malay Peninsula. These are the Semang or Pahang, the Sakai of Tunku, and the Malays. The Semang, as they are mostly usually called by the Malays, are Negritos—a small, very dark people, with features of the negroid type, very prognathous, and with short, woolly hair clinging to the scalp in tiny crisp curls. These people belong to the race which would seem to be the true aboriginal stock of southern Asia. Representatives of it are found scattered about the islands from the Andaman group southwards. The state of civilization to which they have attained is very low. They neither plant nor have they any manufactures except their rude bamboo and rattan vessels, the fish and game traps which they set with much skill, and the bows, blow-pipes and bamboo spears with which they are armed. They are skillful hunters, however, catch fish by ingeniously constructed traps, and live almost entirely on jungle-rootes and the produce of their hunting and fishing. The most civilized of these people is found in Upper Pahang, and the members of this clan have acquired some of the arts of planting. They cannot, however, be taken as typical of their race, and other specimens of this people are seldom seen even by the Sakai. From time to time they have been raided by the latter, and many Negritos are to be found in captivity in some of the Malayan villages on these of the Malay Peninsula.

There is also a small remnant of a large race of people known as the Sakai; they are very dark, very short, and have curiously tapering heads, which is in greatest numbers the country which forms the interior of Pahang, and the valley of Nenggiri in Kelantan. It is about as tall as the average Malay, and altogether have attained in their primitive state to a higher degree of civilization than the Semang. They are about 100,000, and they have mixed somewhat with the Malays, and have acquired some of their customs, and remain distinct from their more civilized neighbours, that they can no longer be regarded as typical of the race to which they belong. The pure Sakai in the interior have a knowledge of plant knowledge of tapioca and other roots, &c, fashion pretty vessels from bamboo, which they decorate with patterns traced by the aid of fire, make loin-cloths (their only garment) from the bark of the 'trae' and other trees; are very musical, using a rude lute of bamboo, and a nose-flute of a very sweet tone, and singing in chorus very melodiously; and altogether have attained in their primitive state to a higher degree of civilization than the Semang.

Archeology.—The only ancient remains found in the peninsula are the stone implements, of which mention has already been made, and some remarkable ancient mines, which are situated in the Jeleu valley in Pahang. The stone implements are generally of one of two types: a long rectangular adze or wedge rudely pointed at one end, and used in conjunction with a mallet or flat stone, and a roughly triangular axe-head, which has evidently been fixed in
cleft of a split stick. A few stones, which might perhaps be arrowheads, have been found, but they are very rare. The mines, which have been constructed for the purpose of working quartz lodes containing gold, are very extensive, and argue a high stage of civilization. They consist of circular or rectangular pits sunk from the cap of a hill, and going down to a depth of in some cases as much as 120 ft., until in fact the miners have been stopped by being unable to cope with the quantities of water shed into the valleys by the rainfall. The shafts are placed so close together that in many instances they are divided by only a couple of feet of solid ground, but at their bases a considerable amount of gallery work has been excavated, though it is now being abandoned. They have been worked systematically as if by some one long since dead and in whose remembrance the natives themselves have placed the gold which originally sank the shafts. Native tradition attributes these mines to the Siamese, but no important case can be attached to this, as it is very general for the Malays to give this explanation for anything. Another theory is that the ancient Romans were the workmen, a theory, which seems to have some probability in its favour, is that these mines were worked by the Kimer people during the period of power, energy and prosperity which found its most lofty expression in the now ruined and deserted city of Angkor Thom; while another attributes these works to the natives of India whose Hindu remains are found in Java and elsewhere, whose influence was at one time widespread throughout Malayan lands, and of whose religious teaching remnants still linger in the superstitions of the Malayas and are preserved in some purity in Lombok and Bali. In the absence, however, of any relics of a kind which might lead to the identification of the ancient miners, their nationality and origin are matters which must continue to be mere questions of speculation and conjecture.

History.—The first hint to reach Europe concerning the existence of habitable lands to the eastward of the Ganges is to be found in the writings of Pomponius Mela (A.D. 43) which speak of Chryse, or the Golden Isle, as lying off Cape Tamus—supposed to be the most easterly point in Asia—and over against the estuary of the Ganges. Thereafter there occur vague references to Chryse in the Peripius of the Erythraean Sea, &c., but the earliest trace of anything resembling first-hand knowledge concerning the peninsula of Indo-China and Malaya is revealed in the works of the early Arab geographers, whose views were derived from those of his predecessor Marinus of Tyre, who in his turn had obtained his deductions from information supplied to him by the mariner Alexander who, there is every reason to think, had himself voyaged to the Malayan Peninsula and beyond. In the light of present knowledge concerning the trade-routes of Asia, which had been in existence for thousands of years are ever Europeans attempted to make use of them, it is safe to identify Ptolemy’s Sinus Perimulicus with the Gulf of Siam, the Sinus Sabaricus with the Straits of Malacca from their southern portals to the Gulf of Martaban, the Aurea Chersonesus with the Malayan Peninsula, and the island of Iabadius or Sabadus—the reading of the name is doubtful—with Sumatra, not as has often been mistakenly attempted with Java. Although the first definite endeavour to locate the Golden Chersonese thus dates from the middle of the 2nd century of our era, the name was apparently well known to the learned of Europe at a somewhat earlier period, and in his Antiquities of the Jews, written during the latter half of the 1st century, Josephus says that Solomon gave to the pilgrims furnished to him by Hiram of Tyre commands “that they should go along with his stewards to the land that of old was called Ophir, but now the Aurea Chersonesus, which belongs to India, to fetch gold.” After the time of Ptolemy no advance in knowledge concerning the geography of southeastern Asia was made until Cosmas Indicopleustes, a monk and an Alexandrian Greek, wrote from personal knowledge between A.D. 530 and 550. His primary object was to prove that the world was built after the same shape and fashion as the Ark made by the Children of Israel in the desert; but he was able to show that the Malayan Peninsula had to be rounded and thereafter a course steered in a northerly direction if China was to be reached. Meanwhile inter-Asiatic intercourse by means of sea-routes had been steadily on the increase since the discovery of the way to utilize the monsoons and to sail directly to and fro across the Indian Ocean (attributed to the Greek pilot Hippalus) had been made. After the decline of the power of Rome, the dominant force in Asiatic commerce and navigation was Persia, and from that time onward until the arrival of the Portuguese upon the scene early in the 16th century the spice trade, whose chief emporia were in or near the Malay Peninsula, was in Persian or Arab hands. There is considerable reason to think, however, that the more frequent ports of call in the Straits of Malacca were situated in Sumatra, rather than on the shores of the Malay Peninsula, and two famous medieval travellers, Marco Polo and Ibn Batuta, both called and wintered at the former, and make scant mention of the latter.

The importance of the Malay Peninsula, as has been noted, consisted in the privilege which its locality conferred upon it of being the distributing centre of the spices brought thither from the Moluccas en route for India and Europe. As early as the 3rd century a.C. Megasthenes makes mention of spices brought to the shores of the Ganges from the southern parts of India, and the trade in question was probably one of the most ancient in the world. So long, however, as India held the monopoly of the clove, the Malay Peninsula was ignored, the Hindus spreading their influence through the islands of the archipelago and leaving traces thereof to this day. The Mahommedan traders from Persia and Arabia, following the routes which had been prepared for them by their forebears, broke down the Hindu monopoly and ousted the earlier exploiters so effectually that by the beginning of the 16th century the spice trade was almost exclusively in their hands. These traders were also missionaries of their religion, as indeed is every Mahommedan, and to them is due the conversion of the Malaya from rude pantheism, somewhat tainted by Hindu mythology, to the Mahommedan creed. The desire to obtain the monopoly of the spice trade has been a potent force in the fashioning of Asiatic history. The Moluccas were, from the first, the objective of the Portuguese invaders, and no sooner had the white men found their way round the Cape of Good Hope and established themselves successively upon the coast of East Africa, in the neighbourhood of the Gulf of Aden and the Malabar coast, than Malacca, then the chief trading centre of the Malayan Archipelago, became the object of their desire. The first Portuguese expedition sent out to capture Malacca was under the command of Diogo Lopez de Siqueira and sailed from Portugal in 1508. At Cochin Siqueira took on board certain adherents of Alphonse d’Albuquerque who were in bad odour with his rival d’Almeida, among them being Magellan, the future circumnavigator of the world, and Francisco Serrão, the first European who ever lived in the Spice Islands. Siqueira’s expedition ended in failure, owing partly to the aggressive attitude of the Portuguese, partly to the very justifiable suspicions of the Malays, and he was presently forced to destroy one of his vessels, to leave a number of his men in captivity, and to sail direct for Portugal. In 1510 a second expedition against Malacca was sent out from Portugal under the command of Diogo Mendez de Vasconcellos, but d’Albuquerque retained it at Cochin to aid him in the retaking of Goa, and it was not until 1511 that the great vicery could spare time to turn his attention to the scene of Siqueira’s failure. After some futile negotiations, which had for their object the recovery of the Portuguese captives before hostilities should begin, an assault was prepared upon Malacca, and though the first attempt to take the city failed and the second attack, made some days later succeeded, both the invaders were driven into European hands. The Portuguese were satisfied with the possession of Malacca itself and did not seek further to extend their empire in Malaya. Instead they used every endeavour to establish friendly relations with the rulers of all the neighbouring kingdoms, and before d’Albuquerque returned to India he despatched embassies to China, Siam, and several kingdoms of Sumatra, and sent a small fleet, with orders to assume a highly conciliatory attitude toward all natives, in search of the Moluccas. Very soon the spice trade had become a Portuguese monopoly, and Malacca was the great headquarters of the trade. It should moreover be noted that Magellan’s famous expedition had for its object not the barren feat of circumnavigation but the breaking down of this monopoly, without violating the terms of the papal bull which gave to Spain the conquest of the West, to Portugal the possession of the East. In 1528 a French expedition sailed from Dieppe, penetrated as far as Achin in Sumatra, but without returning near the Malay Peninsula. It was,
however, the first attempt ever made to defy the papal bull. In 1592, three years after the defeat of the Armada, Raymond and Lancaster rounded the Cape, and after cruising off Penang, decided to winter in Achip. They subsequently hid among the Pulau Sambilian near the mouth of the Perak river, and thence captured a large Portuguese vessel which was sailing from Malacca in company with two Burmese ships. In 1595 the first Dutch expedition sailed from the Texel, but it took a more southerly course than its predecessors and confined its operations to Java and the neighbouring islands. During this period Achip developed a determined enmity to the Portuguese, and more than one attempt was made to drive the strangers from Malacca. Eventually, in 1641, a joint attack was made by the Achinese and the Dutch, but the latter, not the people of the sturdy little Sumatran kingdom, became the owners of the coveted port. Malacca was taken from the Dutch by the British in 1795; was restored to the latter in 1818; but in 1824 was exchanged for Benculuen and a few more unimportant places in Sumatra. The first British factory in the peninsula was established in the native state of Patani on the east coast in 1613, the place having being used by the Portuguese in the 16th century for a similar purpose; but the enterprise came to an untimely end in 1620 when Captain Jourdain, the first president, was killed in a naval engagement in Patani Roads by the Dutch. Penang was purchased from Kedah in 1786, and Singapore from the then sultan of Johor in 1819. The Straits Settlements—Singapore, Malacca and Penang—were ruled from India until 1867, when they were erected into a crown colony under the charge of the Colonial Office. In 1874 the Malay state of Perak was placed under British protection by a treaty entered into with its sultan; and this eventually led to the inclusion in a British protectorate of the neighbouring Malayan States of Selangor, Sungei Ujong, the cluster of small states called the Negri Sambilian and Pahang, which now form the Federated Malay States. By a treaty made between Great Britain and the Sultan of Perak, these states were allowed to exist as a distinct political entity, and the fact that the British now claimed the sultan's subjects as British subjects, was admitted to lie within the Siamese sphere of influence, but by a treaty of 1909 Siam ceded her suzerain rights over the states of Kelantan, Trengganu, Kedah and Perlis to Britain.

Singapore is the political, commercial and administrative headquarters of the colony of the Straits Settlements, and the governor for the time being is ex officio high commissioner of the Federated Malay States, British North Borneo, Sarawak, the Cocos-Keeling and Christmas Islands, and governor of Labuan.

See Sir F. Sweetenham, British Malaya (1906); H. Clifford, Further India (1904); Journal of the Malay Archipelago, Logan (Singapore); Journal of the Straits Branch of the Royal Asiatic Society (Singapore); Weld, Maxwell, Sweetenham and Clifford in the Journal of the Royal Geographical Society (London); Clifford in the Journal of the Royal Geographical Society (London).

MALAYS, the name given by Europeans to the people calling themselves orang Malayu, i.e. Malayon folk, who are the dominant race of the Malay Peninsula and of the Malay Archipelago. Broadly speaking, all the brown races which inhabit the portion of Asia south of Siam and Indo-China, and the islands from the Philippines to Java, and from Sumatra to Timor, may be described as belonging to the Malay family, if the aboriginal tribes, such as the Sakai and Semang in the Malay Peninsula, the Bataks in Sumatra, and the Muruts in Borneo, be excepted. For the purposes of this article, however, only those among these races which bear the name of orang Malayu, speak the Malay language, and represent the dominant people of the land, can be included under the title of Malays. These people inhabit the whole of the Malay Peninsula to the borders of lower Siam, the islands in the vicinity of the mainland, the shores of Sumatra and some portions of the interior of that island, Sarawak and Brunei in Borneo, and some parts of Dutch Borneo, Batavia and certain districts in Java, and some of the smaller islands of the archipelago. Though in these lands they have for not less than a thousand years enjoyed the position of the dominant race, they all possess a tradition that they are not indigenous, and that their first rulers "came out of the sea," with a large band of Malayon warriors in their train. In the peninsula especially, where the presence of the Malays is more recent than elsewhere, many traditions exist which point to a comparatively recent occupation of the country. It has been remarked that there is evidence that the Malays had attained to a certain stage of civilization before ever they set foot in Malaya. For instance, the names which they give to certain fruits, such as the durian, the rambutan and the pulas, which are indigenous in the Malayan countries, and are not found elsewhere, are all compound words meaning respectively the thorny, the hairy and the twisted fruit. These words are formed by the addition of the substantial affix "an"—the use of which is one of the recognized methods by which the Malays turn primitive words into terms of more complex meaning. This may be taken to indicate that when first the Malays became acquainted with the fruits which are indigenous in Malayon lands they already possessed a language in which most primary words were represented, and also that their tongue had attained to a stage of development which produced words by compound and word combination, which are of general usage in Malayan languages.

In the Malayan Peninsula itself there is abundant evidence, ethnological and philological, of at least two distinct immigrations of people of the Malayon stock, the earlier incursions, it is claimed, were due to the arrival of the ancestors of the Orang Asli. The later invasion spreading across the Straits of Malacca from Sumatra at a comparatively recent date. The fact that the semi-wild tribes, which are ethnologically Malayon and distinct from the aboriginal Semang and Sakai, are met with almost invariably in the neighbourhood of the coast would seem to indicate that they reached the peninsula by a sea, not by a land route, a supposition which is strengthened by their almost amphibious habits. Many of these tribes have retained their pristine paganism, but many others it is certain have adopted the Mahommedan religion and have been assimilated by the subsequent and stronger wave of Sumatran immigrants. A study of the local dialects to be met with in some of the districts of the far interior, e.g. the Tembling valley in Pahang, whose people are now Mahommedans and in many respects indistinguishable from the ordinary Malays of the peninsula, reveals the fact that words of this sort, which are not in the archipelago to the south but incomprehensible to the average peninsula Malay, by whom these more ancient populations are now completely surrounded, have been preserved as local words, whereas they really belong to an older dialect once spoken widely in the peninsula, as to-day it is spoken in the Malayon islands. This would seem to show that in some instances the earlier Malayon immigrants fell or were driven by the later invaders back from the coast and sought refuge in the far interior.

Until recently many eminent scientists held the theory that the Malayan peoples were merely an offspring of the Mongol stock, and that their advance into the lands they now inhabit had taken place from the cradle of the Mongolian race—that is to say, from the north. In the fifth edition of his Malay Archipelago, A. R. Wallace notes the resemblance which he traced between the Malays and the Mongolians, and others have recorded similar observations as to the physical appearance of the two races. Today, however, fuller data are available than when Wallace wrote, and the more generally accepted theory is that the Malayon race is ancient, and came from the south, until it was stayed by the Mongolian races living on the mainland of southern Asia. The cranial
measurements of the Malays and an examination of their hair sections seem to bear out the theory that they are distinct from the Mongolian races. Their language, which is neither monosyllabic nor tonic, has nothing in common with that of the Mon-Annam group. It has, moreover, been pointed out that had the Malays been driven southwards by the stronger races of the mainland of Asia, it might be expected that the people inhabiting the country nearest to the border between Siam and Malaya would belong to the Malayan and not to the Mon-Annam or Mon-Khmer stock. As a matter of fact the Sâkai of the interior of the peninsula belong to the latter race. It might also be anticipated, were the theory of a southward immigration to be sustained, that the Malays would be new-comers in the islands of the archipelago, and have their oldest settlements on the Malayan Peninsula. The facts, however, are in exact contradiction to this; and accordingly the theory now most generally held by those who have studied the question is that the Malays form a distinct race, and had their original home in the south. Where this home lay it is not easy to say, but the facts recorded by many writers as to the resemblance between the Polynesian and the Malayan races, and the strong Malayan element found in the languages of the former (see Tregear's Moir and Comparative Polynesian Dictionary, London, 1891), have led some students to think that the two races may have had a common origin.

John Crawfurd, in the Dissertation to his Dictionary of the Malay Language, published in 1840, noted the prevalence of Malayan terms in the Polynesian languages, and attributed the fact to the casting away of ships manned by Malays upon the islands of the Polynesian Archipelago. The appearance of the same Malayan words in localities so widely separated from each other, however, cannot be satisfactorily accounted for by any such explanation, and the theory is now more generally held that the two races are probably allied and may at some remote period of history have shared a common home. It has been suggested that their separation did not take place until after the continent which once existed in the north Pacific had become submerged, and that the Malays wandered northward, while the Polynesians, race spread itself over the islands of the southern archipelago.

All this, however, must necessarily be of the nature of the purest speculation, and the only facts which we are able to deduce in the present state of our knowledge of the subject may be summed up as follows: (a) That the Malays ethnologically belong to a race which is allied to the Polynesians; (b) that the theory formerly current to the effect that the Sakais and other similar races of the peninsula and archipelago belonged to the Malayan stock cannot be maintained, since recent investigations tend to identify them with the Mon-Annam or Mon-Khmer family of races; (c) that the Malays are, comparatively speaking, new-comers in the lands which they now inhabit; (d) that it is almost certain that their emigration took place from the south; and (e) that, at some remote period of their history, they came into close contact with the Polynesian race, probably before its dispersion over the extensive area which it now occupies.

Mohammedans and Mahommedans of the school of Shâhî; and they habitually use the terms Orang Muluay, i.e. a Malay, and Orang Islam, i.e. a Mahommedan, as synonymous expressions. Their conversion from paganism took place during the 13th, 14th, and 15th centuries of our era, and it is believed that those of a different creed is gloated by them into the mosques. The Fast of Ramahâd, however, is generally observed with some faithfulness. Compared with other Mahommedan peoples, the Malays are not fanatical, though occasionally an outbreak occurs in which life is sacrificed by those who have no faith in the holy war. The reason of such outbreaks, however, is usually to be found in political and social rather than in religious grievances. Prior to their conversion to Mahommedanism the Malays were subjected to a considerable Hindu influence, which reached them through means of the traders who visited the archipelago from India. In the islands of Bali and Lombok the people still profess a form of Hinduism, and Hindu remains are to be found in many other parts of the archipelago, though their traces do not extend to the peninsula. Throughout, however, the superstitions of the Malays show indications of a Hindu origin. Their house altars, their idols, their medicine-men invoke their magic practices are clearly borrowed from the pantheon of India. For the rest, a substratum of superstitious beliefs, which survives from the days when the Malays possessed a state religion, is still greatly held in the minds of the people, and the influence of Mahommedanism, which regards such things with horror, has been powerless to eradicate this. Mr. W. W. Skeat's Malay Magic (London, 1900) is a collection of all the Chinese, Malay, and Cochin-China magical beliefs that are practised by the authorities and contains considerable original matter.

The Malays of the coast are a maritime people, and were long famous for the daring character of their acts of piracy. They are noted for their dexterity in fighting use of the hook, which is an article of commerce in the archipelago, and their ingenuity in their calling. Inland the Malays live by preference on the banks of rivers, building houses on piles some feet from the ground, and planting groves of coco-nut, betel-nut, sugar-palm and fruit-trees around their dwellings. Behind these buildings are small fields; the planting of ploughed areas; and the planting of hill-rice by sowing each grain separately in holes bored for the purpose. In the irrigated fields the rice plants are first grown in nurseries, and then transplanted to their permanent beds. The cultivation of spices is a dominant feature in the Malayan races. They are cotton and silk cloths, earthenware and silver vessels, mats and native weapons. The best cotton cloths are those manufactured by the Bugis people in Celebes, and the best cloths which come from Java are striped with patterns. The best silk cloths are produced by the natives of Pahang, Kelantan and Johor in the Malay Peninsula. Lord Leighton pronounced the silver ware from Malaya to be the most artistic of any exhibited at the Colonial Exhibition at South Kensington, London, and it is held by many people, and is greatly admired. When the first Europeans visited the Malay Archipelago the Malays had already acquired the art of manufacturing gunpowder and forging canons. The art of writing also appears to have been independently invented by the Malay races, since numerous alphabets are in use among the peoples of the archipelago, although for the writing of Malay itself the Arabic character has been adopted for some hundreds of years. The Malays are excellent boat-builders. While the Malays were famous almost exclusively for their practical expeditions they naturally bore an evil reputation among Europeans, but now that we have come in closer contact with them, and have learned to understand them better, the old reputation they have acquired is greatly modified. They used to be described as, the most cruel and treacherous people in the world, and they certainly are callous of the pain suffered by others, and regard any strategy of which their enemies are the victims, with open satisfaction. In certain circumstances, however, the Malay is not treacherous, and there are many instances recorded in which men of this race have risked their own lives on behalf of Europeans who chanced to be their friends. They are honest, and are not addicted to gambling or venality. Their own code of manners is minute and strict, and they observe its provisions faithfully. Unlike many Orientals, the Malays can be treated with a friendly familiarity without such treatment being taken for a sign of weakness. Among the Malays, a position of great respect is held, and he who offers assistance is always received as being superior. The Malays are indolent, pleasure-loving, im provident belief, fond of bright clothing, of comfort, of ease, and they dislike toil exceedingly. They have no idea of the value of money, and are content with very small salaries. On the other hand, they always pay much more, seldom as little as four times the value of the goods they purchase. They are much addicted to gambling, and formerly were much given to fighting, though they never display that passion for war in the abstract which is characteristic of some of the white races, and to which they are carried away by the excitement of the battle. It is notorious, however, on the coasts that a Malay gang on board a ship invariably gets the better of any fight which may arise between it and the Chinese crew. The sexual morality of the Malays is very lax, but prostitution is regarded there with disapprobation. The ceremonial of their religion, is practised for the most part among the wealthy classes only. The Malays are an intensely aristocratic people, and show a marvellous loyalty to their rajahs and chiefs. Their respect for rank is not marred by any vulgarity or sordidness. The ruling classes among them display all the vices of the lower classes, and few of the
virtues except that of courtesy. They are for the most part, when left to their own resources, cruel, unjust, selish and improvident.

Much has been written concerning the acts of homicidal mania called amok (omok), which word in the vernacular means to attack. It was formerly believed that these outbursts were to be attributed to madness, par et simile, and some cases of omok can certainly be traced to this source. These are not, however, in any sense typical, and might equally have been perpetrated by men of another race.

The typical amok is usually the result of circumstances which render a Malay man exasperated, and thereupon he assumes a kind of ... the headkerchief, in the view of a European, but to the Malay it is sufficient to make him ....

The nervous affection called latah, to which many Malas are subject, is also a curious trait of the people. The victims of this affection lose for the time all self-control and all sense of their own existence. They are carried away into a sort of trance and, while ... their attention. Accounts of these manifestations will be found in Swettenham’s Malay Sketches (London, 1895) and Clifford’s Studies in Brown Humanity (London, 1897).

The Malays wear a loose coat and trousers, and a cap or head-kerchief, but the characteristic item of their costume is the sarong, a silk or cotton cloth about two yards long by a yard wide, and a quarter wide, the ends of which are sewn together, forming a kind of skirt. This is worn round the waist, leaving the chest bare.

The typical fighting costume of the Malay is a sleeveless jacket with tassets from the shoulders to the waist, the skirt of which hangs freely over the knees. The sarong is tied under the waist, and the coat is furnished with a high collar extending round the back of the neck only. This coat is open in front, leaving the chest bare. The trousers are short and of a peculiar cut and material, usually of cotton. The black or red head kerchief tied like a knot, the women allowing it to fall to the knee, the men, when properly dressed in accordance with ancient custom, folding it over the hilt of their weapon, and draping it around them so that it reaches nearly to the knee. In the hall of a palace a sarong is a symbol of rank and position; it is a symbol of office and a sign of authority; and a person who is ... and the coat is furnished with a high collar extending round the back of the neck only. Costume, Weapons, &c.

The Malay language is a member of the Malay-Polynesian class of languages, which is the representative type of the section which has taken its name from it. The area over which it is spoken comprises the peninsula of Malacca with the adjacent islands (the Rio-Lingga Archipelago, the great island of Sumatra and the separate islands of Java, the Sunda and Banda islands). It is the general medium of communication throughout the archipelago from Sumatra to the Philippines, and it was so upwards of three hundred and fifty years ago that the trade was carried on in the old Malay language.

There are no Malay manuscripts extant, no monumental records with inscriptions in Malay, dating from before the spreading of Islam in the archipelago, about the end of the 13th century. By some it is supposed that the Malay language has been written for as long a period as the Perso-Arabic, but this is of no certain writing prior to the introduction of the Arabic alphabet (W. Robinson, J. de Hollander); whereas others have maintained, with greater show of probability, that the Malays were in possession of an ancient alphabet of their own, of which springs the bunting, or which springs from the Sanskrit (Marsten, Friedricken), as the Kawi (Van der Tuuk), or most like the Lamping (Kern)—all of which alphabets, with the Batag, Bugi and Macassar, are ultimately traceable to the ancient Cambodian alphabet. The new Chinese alphabet was introduced among the Malays; it has continued ever since to be in use for literary, religious and business purposes.

Where Javanese is the principal language, Malay is sometimes found written with Javanese characters; and in Palembang, in the Mentagabo country of Middle Sumatra, the Rechang or Renchong characters are in general use, so called from the sharp and pointed knife with which they are cut on the smooth side of bamboo staves. It is only since the Dutch have established their supremacy in the archipelago that any more use has been made of writing Malay. This is also the case in the Straits Settlements.

By the simplicity of its phonetic elements, the regularity of its grammatical structure, and the copiousness of its nuclear vocabulary, the Malay language is singularly well fitted to be the lingua franca of the eastern seas. It is a language which may perhaps be considered as the most melodic, of a liquid and mute and vice versa, and a liquid and nasal. Final k and h are all but suppressed in the utterance. The only notable mutation of the words is that...
populations for many centuries. These received from them into its vocabulary a large number of Sanskrit terms, from which we can infer the nature of the civilizing influence imparted by the Hindu rulers. Not only in words concerning commerce and agriculture, but also in social, legal, and religious terminologies, one finds indications of a profound influence from ancient India. The Malayan languages have conservative tendencies, and the retention of vestiges of classical Sanskrit and Pali terms is one of their most outstanding characteristics. Among these, the distinction of the Malayan languages from the Chinese, which is often referred to, is significant. The Malayan languages, like those of the Semitic peoples, have a monosyllabic structure, and the absence of the diphthong in the latter is a striking contrast with the former. The Malayan languages also have a distinct acronym, which is a distinguishing feature.

The Malayan language abounds in idiomatic expressions, which constitute a significant feature in its structure. It is in the use of personal pronouns, and prefers impersonal and elliptical diction. As it is rich in specific expressions for the various aspects of certain ideas, it is requisite to employ always the most appropriate terms for conveying the thoughts of the language of the people; its vocabulary is a marvel of the science of words and its words are not borrowed from other languages, and it varies, not only in different localities, but also in the proportion of the individual speaker's acquaintance with Malay proper. The term is used as regards the term Jawi as applied to the Malay language. This has its origin in the names Great Java and Lesser Java, from which the Malay language is derived, and it accordingly means the language spoken along the coasts of the two great islands.

The Malays cannot, strictly speaking, be said to possess a literature, for most of their songs can bear no literary beauty or value. Their most characteristic literature is to be found, not in their writings, but in the fables which they are transmitted orally from generation to generation, and repeated by the wandering minstrels called by the people Madenjaya, Lirai, &c., "soothing of Care." Some specimens of these are to be found in the publications of the Straits Branch of the Asiatic Society (Singapore). The collections of Malay Proverbs made by Klinker, Maxwell, and Clifford also give a good idea of the native method of the Malay. Their verse is of a very primitive description, and is chiefly used for purposes of love-making. There are numerous rhymed fairy tales, which are much liked by the people, but they are of no literary merit.

The literature of the Malays is contained in the Hikayat Abdullah. The latter is a diary of events kept during the civil war in Malaya by a Malay scribe.

developed in the hands of Chinese miners amid the peace and security which British rule has brought to these once lawless lands. The value of the tin output for the year 1905 amounted to $69,466,993 (£,810,490). Although agricultural enterprise in the Malay States is assuming considerable proportions and a growing importance, the total value of the principal agricultural products, including timber, for the year 1905 only aggregated $2,435,513 (£269,143).

The timber of the Malayan Peninsula is one vast forest, through which flow countless streams that form one of the most lavish water-supply systems on earth. When one considers the botany, geology, etc., of the Malay States see MALAY PENINSULA. For the ethnology see MALAYS.)

PERAK is situated between the parallels 3° 37' and 6° 5' N., and 100° 3' to 102° 51' E. on the western side of the Malay Peninsula. It is bounded on the N. by the British possession of Province Wellesley and the Malay state of Kedah; on the S. by the protected native state of Selangor; on the E. by the protected native state of Pahang and the independent states of Kelantan and Petani; and on the W. by the Straits of Malacca.

The coast of Perak is one of the most beautiful that can be found for a distance of some 40 m. from their mouths. In spite of the notable development of tin mining, Perak has still abundant remaining forest. The entire area of the state has as yet been touched either by mining or agricultural enterprise. It is not too much to assert that the larger half of the forest-lands has never been trodden by the foot of man. Thus it is not surprising that the botany and geology of the state are still a very imperfectly known. The forests of the state are divided into the most northerly to the most southerly portions of the state is about 172 m., and the greatest breadth from east to west is about 100 m. The total area of the country is estimated at about 10,000 sq. m.

The Perak river, which runs in a southerly direction almost parallel with the coast for nearly 150 m. of its course, is navigable for small steamers for about 40 m. from its mouth, and by native trading boats for nearly 200 m. The river is crossed by a bridge at Ipoh and a narrow causeway. Planted on the left bank are several important tributaries, all of them falling into the Perak on its left bank. The other principal rivers of the state are the Krian, Kurau, Larut and Bruas to the north of the mouth of the Perak, and the Bernam to the south. None of these rivers of any great importance as a waterway, although the Bernam River is navigable for small steamers for nearly 100 m. of its course. The mountain ranges, which cover a considerable area, run from the north-east to the south-west. The highest altitudes attained by them do not exceed 7500 ft. but for 2000 ft. thickly covered with jungle. The ranges are two, running parallel to one another, with the valley of the Perak between them. The larger is a portion of the main chain, which runs down the peninsula from the west to the east. There are several hills in the vicinity of the rivers, which are covered with vegetation and hills and mountains. There are several hill stations in the state at heights which vary from 2500 to 4700 ft. above sea-level, but the extreme humidity of the atmosphere renders the coolness thus obtainable the reverse of healthy.

Mr. Leonard Wray, curator of the Perak museum, writes as follows on the subject of the geological formation of the state: "The Geology. are really only four formations represented—firstly, the older beds of metamorphic rocks; secondly, a large series of beds of granite; thirdly, a large series of beds of gnaisse, quartzite, schist and sandstone, overlaid in many places by thick beds of crystalline limestone; thirdly, small sheets of trap rock; and fourthly, river gravels and other Quaternary deposits. The granites are of many varieties, and also, in a large number of different geological periods. The series of quartzites, schists, and limestones are really composite, but are not found in any of them, nothing definite can be stated as to their exact chronological position. Their lithological characteristics and occurrence are characteristic of the Archaean period. The failure to discover signs of life in them is, of course, merely negative evidence, and the finding of a single fossil would at once upset it. However, this happens they may be conveniently classified. Classification is at present a rather hazardous business. They are not approaching an accurate estimate of the thickness of this extensive series, but it is probable that it is somewhere between 4000 and 5000 ft. Unconformability has been noticed between the limestones and the granite beds, and there is a noticeable discordance where they rest upon the sandstones and shales. The time of the Perak period is supposed to be a long one, and the Perak rock has been subject to many years yet to come—but to the uncertainty of the labour supply. The mining population is recruited exclusively from the districts of southern China, and during certain years an increased demand for labour in Perak has resulted in the establishment of small colonies in South Africa temporarily and adversely affected immigration to the Straits of Malacca. The output has, moreover, been subject to time from time by the price of tin, which was $3.20 per hundredweight in 1896, rose to $4.25 in 1898, to $7.14 in 1900, and averaged $4.18 in 1902. The output of tin from Perak ranged between 18,600 tons, valued at $23,950,566 in 1899, and 26,600 tons, valued at $35,500,000, in 1905. The fluctuating character of the output is due, not to any exhaustion of the mineral deposits, but to the uncertainty of the labour supply. stick (of which the Perak is a large producer) has been valued at $108,000 worth of Para rubber, $181,000 of copra, $53,000 of cotton, $26,600 of patchouli, and considerable quantities of timber, rattans and other jungle produce. The agricultural development of the state has been steadily progressing in the last few years, with increasing areas, and the known fertility of the soil, the steady and regular rainfall, the excellent means of communication, and the natural and artificial conditions of the country, justify the expectation that the future prosperity of the state will be even greater.

Although so much has been done to develop the resources of Perak, by far the greater portion of the state is still covered by dense and virgin forest. In 1890 it was estimated that only 30,000 acres of land were occupied or cultivated out of a total acreage of 6,000,000.

The early history of Perak is obscure, the only information on the subject being obtained from native traditions, which are altogether untrustworthy. According to these authorities, however, a settlement was first made by Malays in Perak at Brus, and the capital was later moved to the banks of the Perak River, the site chosen being a little village called Temonggong, which lies some miles up stream from Kuala Kangsar, the present residence of the Sultan. When the Malacca sultaneate fell, owing to the invasion of the Portuguese in 1511, a member of that royal house is said to have migrated to Perak, and the present dynasty claims to have descended from him. As this boast is also made by almost every ruling family in the peninsula, the tradition is not worthy of any serious credit. The movement of the capital has been taken by the Chinese as a sign of the coming of the great year of the Chinese calendar, and the new capital is considered more favorable for the birth of children, who are thus prevented from going to the old one and being born.
The area of agricultural holdings has notably increased, but a considerable period must yet elapse before it will amount to even one-tenth of the whole. A line of railway connects the port of Teluk Anson with the great mining district of Kinta, whence the tin runs, crossing the Perak River at Ent Swettenham, Kangsar, the residence of the sultan, thence to Taiping, the administrative capital of the state, and via Krian to a point opposite to the island of Penang. A second line runs south from Perak and connects with the railway system of Selangor, which in its turn connects with the Penang line. The Perak River, also, is esp. valuable for the communication between the last-mentioned name and Penang. Perak also possesses some 600 miles of excellent metalled cart-road, and the length of completed road is annually increasing.

For the revenue of Selangor in 1875 amounted to $315,938, derived from customs, and $3,717,238 on account of federal charges, and $1,972,628 from federal receipts, and $540,360 from land revenue. The expenditure for the same year was $2,686,316, making a total of $5,316,955, equivalent to £5,988,000. The principal export is tin, valued at $1,972,628. The value of the imports in 1905 was $24,043,610. The exports of tin in 1905 amounted to 68,573 cwt., valued at $53,166,955.

Selangor is situated between the parallels 2° 32' and 3° 37' N. and 106° 38' and 107° 10' E., on the western side of the Malay Peninsula. It is bounded on the N. by the protected native state of Perak, on the S. by the protected states of Negri Sembilan, on the E. by Pahang and the Negri Sembilan, and on the W. by the Straits of Malacca. The coast-line is about 100 m. in length, greatest length about 104 m., and greatest breadth about 48 m., total area estimated at about 3000 sq. m.

The state consists of a narrow strip of land between the mountain range which forms the backbone of the peninsula and the Straits of Malacca. Compared with other states in the peninsula, Selangor is poorly watered. The rivers are few. The principal river is the Klang; it is situated at the mouth of the Klang River, and is connected with the capital, Kuala Lumpur, by a railway. The state is possessed of most valuable deposits of alluvial tin, and mining for this metal has been carried on for many years. The principal centres of mining activity are Kuala Lumpur and the Negri Sembilan.

According to native tradition, the ruling house of Selangor is descended from a Bugis raja, who, with two of his brothers, settled in the area in 1875. These brothers eventually became the rulers of the state.

History.

Selangor, situated between the parallels 2° 32' and 3° 37' N. and 106° 38' and 107° 10' E., on the western side of the Malay Peninsula.

The state consists of a narrow strip of land between the mountain range which forms the backbone of the peninsula and the Straits of Malacca. Compared with other states in the peninsula, Selangor is poorly watered. The rivers are few. The principal river is the Klang; it is situated at the mouth of the Klang River, and is connected with the capital, Kuala Lumpur, by a railway. The state is possessed of most valuable deposits of alluvial tin, and mining for this metal has been carried on for many years. The principal centres of mining activity are Kuala Lumpur and the Negri Sembilan.

According to native tradition, the ruling house of Selangor is descended from a Bugis raja, who, with two of his brothers, settled in the area in 1875. These brothers eventually became the rulers of the state.
18th century a rajah of the royal house of Menangkabu came from Sumatra to rule over the federation of small states, each of which continued to be governed in all its local affairs by its own chief and by the village and other councils sanctioned by ancient custom. The Sumatran rajahs also contributed to the confederacy. Although they bore the name of the "Nine States," only six seem to have belonged to the federation during the time of which history speaks. These are Sri Menanti, Johol, Tampin, Rembau, Jebeul, and Segamat. At a certain time, the state of Perak seceded from the confederation. Ancient tradition says that the names of the nine states were originally Klang, Jebeul, Sungei Ujong, Johol, Segamat, Pasir Besar, Nanging, Rembau and Jelai. Of these Klang was the most important. It was the ancient capital of the Selangor. The name of the district is still retained by several places in the province of the state of Nanking by Malacca. During the last years of the 18th century the Iang-di-per-Tuan appointed an Iang-di-per-Tuan Muda to rule Rembau, and the state of Tampin was created to provide for the families of the princes who had contributed to the formation of the confederation. These states were founded by Tampin, a native of the Selangor, and his two sons, who respectively inherited the titles of the states of Tampin and Jebeul.

The population of the Negri Semilan, which according to the census taken in April 1891 was only 70,750, is made up of various elements, including the people of the British, the Chinese and the Malay. The Chinese are the majority, and are divided mainly as follows: — customs 1,269,622, land revenue $415,475, land sales $21,407, while the revenue 1891 amounted $344,489. The expenditure in 1895 amounted 321,043, of which $1,251,055 was expended on public works. The trade returns for 1903, which are not complete, show an aggregate of about $30,000,000. The value of the tin exports is not as high as the expenditure on the agricultural produce, of which gambier represented $211,000 and damar $80,000, amounted to $407,990.

General.

The administrative capital of the Negri Semilan, is connected to the coast by the Negri Semilan Railway Company, which is 24 miles in length. It is also situated on the trunk line of the Federal Malaya States, and is thus joined by rail to Selangor on the north, and the Federated Malay States on the south. The line is only maintained between Port Dickson and the ports on the Straits of Malacca and with Singapore.

For administrative purposes the Negri Semilan is divided into five districts, viz., the Selangor District, the Coast District, the Kuala Pilah and Tampin. Each of these is under the charge of a European district officer, who is responsible to the Resident. The Iang-di-per-Tuan lives at Kuala Pilah, but the capital of the federation is at Seremban, which the state of Selangor, with its secondary residence of Kuantan, is divided into the two main divisions of the Selangor, is one of the pleasure resorts of this part of the peninsula.

Pahang, on the east coast of the peninsula, is situated between parallels 2° 28' and 3° 45' N. and 101° 30' and 102° 30' E. It is bounded by the Japanese natives of Perak and Selangor. The coast-line is about 112 m. in length, the greatest length is about 210 m., and greatest breadth about 130 m. The state is the largest in the peninsula, its area being estimated at 15,000 sq. m. The ports on the coast are the mouths of the Endau, Rompin, Pahang and Kuantan rivers, but during the north-east monsoon the coast is not easy of approach, and the rivers, all of which are guarded by difficult bars, are impossible of access except at high tides.

The principal river of the state is the Pahang, from which it takes its name. At a distance of 180 m. from the coast this river is formed by two other named respectively the Helai and the Tembeling. The former is joined 20 m. farther up stream by the Buloh, the latter by the rivers which rise in the hills which separate Pahang from Selangor. The Tembeling has its rise in the hills which divide Pahang from Selangor, but some of its tributaries rise on the Trengganu frontier, and the Buloh rises in the hills through which the Kuantan River takes its rise. The Pahang is navigable for large boats as far as Kuala Lipis, 200 m. from the mouth, and light-draft launches can also get up to that point. Smaller boats go as far as Baling, which is 70,730, for the river, however, has a sandy beach fringed with casuarina trees and there are only a few patches of mangrove-swamp throughout its entire length.

The ancient name of Pahang was Indrapura. It is mentioned in the history of Sang Tua, the great Malacca brave, who flourished in the time of the sultan of Siam, which is now the site of the then ruling house of Pahang for his master, the sultan of Malacca. Prior to this, Pahang had been ruled by the Siamese. When Malacca fell into the hands of the Portuguese in 1511, the sultan of Siam, who lived in the city of Negri Semilan, which was inhabited by the British, was obliged to accept the authority of the Portuguese. In 1521, the Portuguese gave to the sultan of Siam a certain amount of money, and this is the origin of the present name of Pahang.

The ceded area in April 1901 gave the total population of Pahang consisting of 84,113, of whom 73,492 were Malays, 8965 Chinese, 1227 Tamils and other natives of India, 1168 Europeans and 496 of other nationalities. The population in 1905 was estimated at 100,000, the increase being due to immigration mainly from the states on the western seaboard. In former days Pahang had been far more populous, but the long succession of civil wars which racked the land after the death of the sultan of Pahang, which was 1897, was the end of the British control of the state. The British were succeeded by the sultan of Pahang, whose name was merged into the tradition of the sultan of Pahang, and whose history is that of the sultan of Pahang. The ceded area in April 1901 gave the total population of Pahang consisting of 84,113, of whom 73,492 were Malays, 8965 Chinese, 1227 Tamils and other natives of India, 1168 Europeans and 496 of other nationalities. boundaries are inhabited by Pahang Malays, the descendants of these fugitives. The Pahang natives are also almost all engaged in agriculture. The work of the mines, &c, is performed by Chinese and foreign Malays. In the Lipis valley the descendants of the Kawai tribe live. In the interior of the land, which is inhabited in defiance of the Pahang rajas, still outnumber the people of the land.

The revenue of Pahang in 1890 amounted to only $62,077; in 1900 to $410,150. In 1905 it was $528,368. The expenditure in 1905 amounted to $1,208,176. Of this sum $736,886 was expended on public works. Pahang is still a source of expense to the federation, its progress having been retarded by the expenses of the war between the Pahang and the Kelantan. It has not, of course, been financed in full for many years. Its trade is increasing, but the revenue is now steadily increasing, and the ultimate financial success of the state is considered to be secure. Pahang owes something over $1,996,180 to the government of the States. Its salted fish industry has brought a revenue of over $2,820,745. The value of the exports of 1905 was $1,344,346, of which the exports of Chinese goods amounted to $3,838,928, thus making a total trade value of $5,193,274. The most valuable article is tin, the value of which in 1905 amounted to $2,820,745. The value of the gutta percha exceeded $140,000, that of dried and salted fish amounted to nearly $70,000, and that of timber to $325,000.

The geological formation of the states lying to the eastward of the main range of mountains which splits the peninsula in twain differs materially from that of the western states. At a distance of about a dozen miles from the summits of the mountains there is a district of low-lying country, in many places intersected by fissures of quartz, and in others overlaid by vast thicknesses of limestone. Those of the quartz fissures which have been exploited are found to be auriferous, and several districts have already been worked for gold.

Their efforts, however, have not hitherto been successful. A magnificent road over the mountains, with a ruling grade of 1 in 30, joins Kuala Lipis, the administrative capital of Pahang, to Kuala Kubi, the chief town of the Pahang state, and this road is now being extended in length. Pekan, where the sultan has his residence, was the capital of Pahang until the middle of 1898, when the administrative headquarters were transferred to the interior as being more central. Now, the capital is at Kuala Kubi, which has many public and private buildings.

In the Nielson valley, which lies parallel to the Pahang River, a European company is working tin lodes with considerable success. These lodes are only the mines of the kind being worked in the Federated Malay States. Pahang has little, and is not suitable for agriculture of many kinds, in length. Pekan, where the sultan has his residence, was the capital of Pahang until the middle of 1898, when the administrative headquarters were transferred to the interior as being more central. Now, the capital is at Kuala Kubi, which has many public and private buildings.

The rainfall is heavy and regular. The climate is cooler than that of the west coast, and the full force of the monsoon is felt from October to February in each year. For administrative purposes, Pahang is divided into four districts—Ulu Pahang, in which the present capital is situated; Temerloh, which includes 80 miles of the Pahang valley and the Semantan River; Pekan, which includes the coast rivers down to Endau; and Kuantan. Each of these districts is under the charge of a district officer, who, whenever necessary, is the resident. The boundary with Johor and the Negri Sembilan was rectified by a commission which sat in London in 1897--1898.

II. NON-FEDERATED STATES

In 1909 a treaty was made between Great Britain and Siam, one provision of which was that the cession to the former of the suzerain rights enjoyed by the latter over certain territories in the Gulf of Siam, known as the Burmese Archipelago, was to be taken into consideration as the acquisition of the islands by the British government, and that the suzerain rights of Siam were to be transferred to the new government. The cession of these islands to the British government was finally completed in 1909, and the islands were ceded to the British government, the islands of Kedah, Perlis, and Trengganu being thus added to the Federation of Malaya.

The cession of these islands to the British government was finally completed in 1909, and the islands of Kedah, Perlis, and Trengganu being thus added to the Federation of Malaya.

The only island among the British possessions in the British Archipelago is the island of Singapore, which was ceded by Siam in 1875.

The islands of the Malayan Archipelago are inhabited by a people who are of Malay origin, and who are known as the Malays. The Malays are divided into two main groups, the Siamese and the Chinese. The Siamese are the inhabitants of the southern part of the Malay Peninsula, and are the most numerous of the two groups. The Chinese are the inhabitants of the northern part of the Malay Peninsula, and are the most industrious of the two groups.

COMMONWEALTH OF MALAYSIA

MELAKA

Melaka...
MALAY STATES (SIAMESE).

The authority which, at one time covered the whole of the Malay peninsula, now extends southward along an irregular line drawn across the peninsula at about 6° 30' N. Between Patani and the Isthmus of Kra, usually accepted as the northernmost point of the Malay Peninsula, there lie some 20,000 sq. m. of territory inhabited by a mixed population of Siamese and Malays; and there a few remnants of the aboriginal inhabitants clinging to the wilder districts, and with a few Chinese settlers engaged in commerce. Formerly this tract was divided into a number of states, each of which was ruled by a chief (Siamese, Chao Muang; Malay, raja), who held his title from the king of Siam, but, subject to a few restrictions, conducted the affairs of his state in accordance with his own desires; the office of chief, moreover, was hereditary, subject always to the approval of the suzerain. The states formed two groups: a northern, including Langsuan, Chaya, Nakhon Sri Tammarat, Songkla, Renang, Takoa, Pang Nga, Tangka and Trang, in which the Siamese element predominated and of which the chiefs were usually Siamese or Chinese; and a southern, including Palem, Satun (Setul), Patani, Raman, Jering, Sai (Teloban), Be Nge (Legeb), Yala (Jalor) and Nong Chik, in which the population was principally Malay and the ruler also Malay. Four other states of the southern group, Kelantan, Trengganu, Kadah and Perlis, of which the population is entirely Malay, passed from Siamese to British protection in 1909.

With the gradual consolidation of the Siamese kingdom all the states of the northern group have been incorporated as ordinary provinces of Siam (q.v.), the hereditary Chao Muang having died or been pensioned and replaced by officials of the Siamese Civil Service, while the states themselves now constitute provinces of the administrative divisions of Chumphon, Nakhon Sri Tammarat and Puket. The states of the southern group, however, retain their hereditary rulers, each of whom presides over a council and governs with the aid of a Siamese assistant commissioner and with a staff of Siamese district officers, subject to the general control of the Siamese high commissioner at Bangkok, or, in the case of Perak and Kelantan, and, cancelling the authority of Kadah, to place him to some extent under the orders of the high commissioner of Songkla. By the terms of the Anglo-Siamese treaty of 1909 about half of the state of Perak was ceded to the British government by which the importance of the latter was considerably increased.

Patani.—The seven Malay states of Nang Chik, Patani, Jering, Yala (Jalor), Sai (Teloban), Raman and Ra-ngé (Legeb) were converted into a British protectorate by means of a treaty of 1896 between the Siamese high commissioner, and many of the ancient privileges and customs of Malay government are preserved. The group of states is situated between 5° 34' and 6° 52' N. and 100° 54' and 101° 8' E. It is bounded N. by the China Sea, E. by the China Sea and Kelantan, S. by Perak, and W. by Kadah. The total area is about 333,000 sq. m. The country is mountainous except close to the coast. The chief rivers are the Chik and the Patani, and many others are navigable and shallow, and navigable for small boats only. The population is about 335,000, of whom the great majority are Malays. Each state has its capital, but Patani (the headquarters of the high commission) is by far the largest. Composed of Siamese and Chinese, it is poor and is chiefly by river, but roads are under construction. Patani and Sai are in telegraphic communication with Bangkok and Singapore, and regular weekly mails are despatched to those places. The chief crops are rubber, pepper, and rice, and the trade is largely with Singapour and in Nang Chik, where much rice is grown. Tin mining is a growing industry; many Chinese own mines and several European syndicates are at work in Kau, Ra-ngé and Patani, prospecting for, or mining, chicle. Misrule continues and is partly due to the absence of European control of the population. The annual export of tin is about 400 tons, and dried fish, salt, cattle and elephants are other exports. Steamers up to 300 tons maintain frequent communication with Bangkok and Singapore, and the Patani roads afford good anchorage at all seasons.

Mahomedan law is followed in the settlement of inherited property disputes and of matrimonial affairs; otherwise the laws of Siam obtain. Efficient law courts have been established in each state, and there is a serviceable force of gendarmerie recruited from amongst Malays and Siamese alike. The revenue amounts to about 600,000 ticals, or £45,000 a year, one-third being payable to the rulers as private income for themselves and their relatives, one-third expended on the public, or, if surplus, returned to the rulers for special purposes, but it is usually found necessary to devote the last-mentioned third to the expenses of administration. Patani has been subject to Siam from the remotest times. It is said that the old state of Patan, which included the whole of Upper Patani and the south of the Kelantan peninsula, was ruled by the Kings of Siam, embracing that religion and at the same time revolving to Malacca. It has several times been necessary to send punitive expeditions to recall the state to its allegiance. The present rulers are ostensibly descendants of those ruling families of the old state of Kelantan, but the chief of Patani itself is a member of the family which ruled there in the days of its greatness. Throughout the 17th century Patani was restored to Portuguese, Dutch and English merchants, who established a large slave trade as an emporium for trade with Siam. In 1641 an engagement took place in the Patani roads between three Dutch and two British ships, the latter being after the president of the British merchants, John Jourdain, had been killed. In 1680 the border between the state of Perak and Patani was fixed by an agreement between England and Siam, a dispute of old standing being thereby settled, but the question was reopened in the negotiations which preceded the Anglo-Siamese treaty of 1909, when a new border line was fixed between British and Siamese possessions in the peninsula.

MALCHIN, a town of Germany, in the grand-duchy of Mecklenburg-Schwerin, on the river Peene, between lakes Malchin and Kummerow, 28 m. by rail N.W. of Neu-Brandenburg. Pop. (1900), 7449. It is, alternately with Sternberg, the place of assembly of the Diet of Mecklenburg. Here are the chateaux of Remplin, Basedow and Schlitz; a church dating from the 14th century, and a fine town-hall. The well-wooded and undulating country, environs the shores of Lake Malchin, is known as the "Mecklenburg Switzerland," and is increasing in favour as a summer resort. A canal unites Lake Kummerow with the Peene. The industries of the town include the manufacture of sugar and bricks, and brewing and malting. Malchin became town in 1236.

MALCOLM, the name of four kings of the Scots, two of whom, MALCOLM I., king from 943 to 954, and MALCOLM II., king from 1034 to 1034, are shadowy and unimportant personages.

MALCOM III. (d. 1035), called Canmore or the "long-headed," was a son of King Duncan I., and became king after the defeat of the usurper Macbeth in July 1034, being crowned at Scone in April 1037. Having married as his second wife, (St) Margaret (q.v.), sister of Edgar Etheling, who was a fugitive at his court, he invaded England in 1070 to support the claim of Edgar to the English throne, returned to Scotland with many captives after harrying Northumbria. William the Conqueror answered this attack by marching into Scotland in 1072, whereupon Malcolm made peace with the English king at Abercraeth, near Abergele. After this he, with the approval of his wife, ravaged the north of England again and again, until in 1091 William Rufus invaded Scotland and received his submission. Then in 1092 a fresh dispute arose between the two kings, and William summoned Malcolm to his court at Gloucester. The
MALCOM, SIR J.—MALEN

Scot obeyed, and calling at Durham on his southward journey was present at the foundation of Durham Cathedral. When he reached Gloucester Rufus refused to receive him unless he did homage for his kingdom; he declined and returned home in high dudgeon. Almost at once he invaded Northumbria, and was killed at a place afterwards called Malcolm's Cross, near Alnwick, on the 13th of November 1093. Four of Malcolm's sons, Duncan II., Edgar, Alexander I., and David I., became kings of Scotland; and one of his daughters, Matilda, became the wife of Henry I. of England, a marriage which united the Saxon and the Norman royal house.

MALCOM IV. (c. 1141–1165) was the eldest son of Henry, 1 earl of Huntingdon (d. 1152), son of King David I., and succeeded his grandfather David as king of Scotland in 1153. He is called the "Maiden," and died unmarried on the 9th of December 1165.

See E. A. Freeman, The Norman Conquest, vols. iv. and v. (1867–1879), and The Reign of William Rufus (1882); W. F. Scene, Celtic Scotland (1876–1886); E. W. Robertson, Scotland under her Early Kings (1862); and A. Lang, History of Scotland, vol. i. (1900).

MALCOM, SIR JOHN (1799–1833), Anglo-Indian soldier, diplomatist, administrator and author, was born at Burnfoot on the Esk, near Langholm, Dumfriesshire, Scotland, on the 2nd of May 1799. His father was a humble farmer, but three of his sons attained the honour of knighthood. At the age of twelve he received a cadetship in the Indian army, and in April 1783 he landed at Madras, shortly afterwards joining his regiment at Vellore. In 1792, having for some time devoted himself to the study of Persian, he was appointed to the staff of Lord Cornwallis as Persian interpreter, but two years afterwards was compelled by ill health to leave for England. On his return to India in 1796 he became military secretary to Sir Alured Clarke, commander-in-chief at Madras, and afterwards to his successor General Harris; and in 1798 he was appointed by Lord Wellesley assistant to the resident at Hyderabad. In the last-mentioned capacity he highly distinguished himself by the manner in which he gave effect to the difficult measure of disbanding the French corps in the pay of the nizam. In 1799, under the walls of Seringapatam, began his intimacy with Colonel Arthur Wellesley, which in a short time ripened into a life-long friendship. In the course of the same year he acted as first secretary to the commission appointed to settle the Mysore government, and before its close was appointed by Lord Wellesley to proceed as envoy to the court of Persia for the purpose of counteracting the policy of the French by inducing that country to form a British alliance. Arriving at Teheran in December 1800, he was successful in negotiating favourable treaties, both political and commercial, and returned to Bombay by way of Bagdad in May 1801. He now for some time held the interim post of private secretary to Lord Wellesley, and in 1803 was appointed to the Mysore residency. At the close of the Mahatta War, in 1804, and again in 1805, he negotiated important treaties with Sindia and Holkar, and in 1806, besides seeing the arrangements arising out of these alliances carried out, he directed the difficult work of reducing the immense body of irregular native troops. In 1808 he was again sent on a mission to Persia, but circumstances prevented him from getting beyond Bushire; on his reappointment in 1810, he was successful indeed in procuring a favourable reception at court, but otherwise his embassy, if the information which he afterwards incorporated in his works on Persia be left out of account, was (through no fault of his) without any substantial result. He sailed for England in 1811, and shortly after his arrival in the following year was knighted. His intervals of leisure he devoted to literary work, and especially to the composition of a History of Persia, which was published in two quarto volumes in 1815. On his return to India in 1817 he was appointed by Lord Moira his political agent in the Deccan, with eligibility for military command; as brigadier-general under Sir T. Hislop he took a distinguished part in the victory of Mchidpur (December 21, 1817), as also in the subsequent work of following up the fugitives, determining the conditions of peace and settling the country. In 1821 he returned once more to England, where he remained until 1827, when he was appointed governor of Bombay. His influence in this office was directed to the promotion of various economical reforms and useful administrative measures. Leaving India for the last time in 1830, he shortly after his arrival in England entered parliament as member for Launceton, and was an active opponent of the Reform Bill. He died of paralysis on the 30th of May 1833.

Besides the work mentioned above, Sir John Malcolm published Sketch of the Political History of India since . . . 1764 (in 1811 and 1826); Sketch of the Sikhs (1812); Observations on the Disturbances in the Persian Army in 1800 (1812); Persia, a Poem, anonymous (1824). A Memoir of Central India (2 vols., 1825); and Sketches of Persia, anonymous (1827). A posthumous work, Life of Roberti, Lord Clive, appeared in 1836. See Life and Correspondence of Sir John Malcolm, by J. W. Kaye (2 vols., 1856).

MALDA, a district of British India, in the Rajahji division of Eastern Bengal and Assam. Area, 1899 sq. m.; pop. (1901), 584,930, showing an increase of 8·5 in the decade. The administrative headquarters are at English Bazar (pop. 13,667) near the town of Old Malda. The district is divided into two almost equal parts by the Mahananda river, flowing from north to south. The western tract between the Mahananda and the main stream of the Ganges is an alluvial plain of sandy soil and great fertility. The eastern half is an elevated region broken by the deep valleys of the Tangan and Purnabhaba rivers and their small tributary streams. The soil here is a hard red clay; and the whole is overgrown with thorny tree jungle known as the kāalī. Agricultural prosperity centres on the Mahananda, where mango orchards and high raised plots of mulberry land extend continuously along both banks of the river. The Ganges nowhere intersects the district, but skirts it from its north-western corner to the extreme south. The Mahananda flows in a deep well-defined channel through the centre, and joins the Ganges at the southern corner. Its tributaries are the Kalindri on the right, and the Tangan and Purnabhaba on the left bank. The two principal industries are the production of indigo and silk. The first has declined, and so has the second as far as concerns the weaving of piece goods, but the rearing of silkworms and the export of raw silk and silk thread are carried on upon a large scale. No railway touches the district, but the communications by water are good.

Malda supplied two great capitals to the early Mahomedan kings of Bengal; and the sites of Gaur and Pandua exhibit the most interesting remains to be found in the lower valley of the Ganges. (See Bengal and its Annals, A.D. 1305-1664; and idem, A.D. 1576-1800, 2 vols., 1832.) As far back as 1676 there was a factory there. In 1770 English Bazar was fixed upon for a commercial residency, the buildings of which at the present day form both the public offices and private residence of the collector.

MALEN, a city, including several villages, of Middlesex county, Massachusetts, U.S.A., on the Malden river, about 5 m. N. of Boston. Pop. (1890), 23,031, (1900), 33,664, of whom 9513 were foreign-born, 3673 being English Canadians, 870 English, and 617 Swedes; (1910 census) 44,404. Malden had in 1906 a land area of 4·78 sq. m. It is served by the Boston & Maine railroad, and by inter-urban electric railways. Although it is largely a residential suburb of Boston—its post office is a Boston sub-station—it has important manufacturing industries. The most valuable manufactured product is rubber boots and shoes. The capital invested in manufacturing in 1905 was $5,553,432; and the value of the factory product, $11,235,035, was 10·2% greater than the value of the factory product in 1900. Among Malden's institutions are the public library (endowed by Ellisha S. Converse), the Malden hospital, the Malden day nursery, a Young Men's Christian Association, and a home for the aged. A fine system of parks is maintained; the best known is possibly Pine Banks. To the north and west is the Middlesex Fells, a state reservation; about 60 acres of this and about 20 acres of the Middlesex Fells Parkway lie within Malden. Malden, when first settled about 1640, was part of Charlestown, and was known for some years as Mystic Side. It was incorporated as a town under the name of "Mauldon" in 1649, and was chartered as a city in 1881. The north part of Malden was set off in 1890 to form Melrose, and the south part
MALDIVE ISLANDS—MALEBRANCHE

in 1870 to form the town of Everett. Malden was the birthplace of Adoniram Judson, the “apostle to Burma.” Michael Wigglesworth was pastor here from 1656 until 1705.

See D. P. Corey, History of Malden (Malden, 1893); and Malden, Past and Present (Malden, 1895).

MALDIVE ISLANDS, an archipelago of coral islets in the Indian Ocean, forming a chain between 7° 6’ N. and 6° 42’ S. It consists of seventeen atolls with an immense number of islands, of which some three hundred are inhabited. In the extreme south are the isolated atolls of Addu and Fua-Mulaku, separated from Suvdiva by the Equatorial Channel, which is itself separated from the main chain of atolls by One-and-a-half-degree Channel. Following the chain northward from this channel we have Haddumati and Kolumadulu, after which the chain becomes double: to the east the chief atolls are Mulaku, Fadiffolu, South Male’, North Male’, Kardiva (where the channel of the same name, 35 m. broad, partly breaks the chain), and Fadiffolu. To the west are South Nilandu, North Nilandu, Ari, South Malhos, North Malhos and Miladumadulu. To the north again are Tidal Pati and Thanadifu. Finally, to the north of Eight-degree Channel is Minikoi, 71 m. from the nearest peak of the Maldivian archipelago, from which the Laccadives to the north. The main part of the archipelago, north of One-and-a-half-degree Channel, consists of a series of banks either surrounded or studded all over with reefs (see J. S. Gardiner, “Formation of the Maldive Islands,” in Geographical Journal, xix. 277 seq.). Mr Gardiner regarded these banks as plateaus rising to different elevations beneath the surface of the sea from a main plateau rising steeply from the great depths of the Indian Ocean.

After the Portuguese, from about 1518 onwards, had attempted many times to establish themselves on the islands by force, and after the Maldivians had endured frequent raids by the Mopla pirates of the Malabar coast, they began to send tokens of homage and claims of protection (the first recorded being in 1643) to the rulers of Ceylon, and their association with this island has continued practically ever since. The hereditary sultan of the archipelago is tributary to the British government of Ceylon. The population of the Maldives is estimated at 30,000. All are Maldivians. By Messrs. Gardiner and Cooper they are classed in four ethnological divisions. (1) Those of the atolls north of the Kardiva Channel. Here the reefs are generally less perfect than elsewhere, seldom forming complete central lagoons, and as they were formerly exposed to the constant attacks of the Mopla pirates from India, the people are harder and more vigorous than their less warlike southern neighbours. They annually visited the coasts of India or Ceylon, and often married Indian wives, thus acquiring distinct racial characters of an approximately Dravidian type. (2) Those of the central division, comprising the atolls between North Male’ and Haddumati, who are under the direct rule of the sultan, and have been more exposed to Arab influences. They formerly traded with Arabia and Malaya, and many Arabs settled amongst them, so that they betray a strong strain of Semitic blood in their features. (3) and (4) The natives of Suvdiva, Addu, Mulaku and the other southern clusters, who have lived in isolation with the Central Malé people, and probably preserve more of the primitive type, approximating in appearance to the Sinhalese villagers of Ceylon. They are an intelligent and industrious people, growing their own crops, manufacturing their own cloth and mats, and building their own boats, while many read Arabic more or less fluently, although still believers in magic and witchcraft. The language is a dialect of Sinhalese, but indicating a separation of ancient date and more or less mahomedanized.

The sultan’s residence and the capital of the archipelago is the island of Male’. From the earliest notices the production of coir, the collection of cowries, and the weaving of excellent textures on these islands have been noted. The chief exports of the islands besides cowrie and cowries (a decreasing trade) are coco-nuts, copra, tortoise-shell and dried bonito-fish.

Minikoi atoll, with the numerous wrecks on its reefs, its light-house, and its position on the track of all eastward-bound vessels, is a familiar sight to seafarers in these waters. The atoll, which is pear-shaped and disposed in the direction from S.W. to N.E. is 5 m. long, with an extreme breadth of nearly 3 m., with a large but shallow lagoon approached from the north by a passage two fathoms deep. The atoll is growing outwards on every side, and at one place rises 10 ft. above sea-level.

The population, which numbers about 3000, is sharply divided into five castes, of which the three highest are pure Maldivians, the lower two the same as in the Laccadives. All are centred in a small village opposite Mou Rambou Point on the west or lagoon side; but most of the men are generally absent, many being employed with the Lascar crews on board the large liners plying in the eastern seas.

In 1899-1900 Messrs. J. Stanley Gardiner and C. Forster Cooper carried out an expedition to the Maldives and Laccadives, for the important results of which see The Fauna and Geography of the Maldivian and Laccadive Archipelagos, ed. J. S. Gardiner (Cambridge, 1901-1905), also Proceedings of the Cambridge Philosophical Society, vol. x. pt. 1 (1900), and the Geographical Journal, loc. cit., 8c. A French adventurer, Francois Pyard de la Val, was wrecked in the Maldives in 1602 and detained there five years; he wrote an interesting account of the archipelago, Voyage de F. P. de la Val (Paris, 1608), in which he describes the island of Minikoi, and also A. Agassiz, “An Expedition to the Maldives” in Amer. Journ. Science, vol. xiii. (1902).

MALDON, a market town, municipal borough and port, in the Maldon parliamentary borough of Essex, England, on an activity rising from the south side of the Blackwater, 43 m. E.N.E. from London by a branch from Witham of the Great Eastern railway. Pop. (1901), 5565. There are east and west railway stations. The church of All Saints, dating from 1056, but, as it stands, Early English and later, consists of chancel, nave and aisles, with a triangular Early English tower (a unique form) at the west end surmounted by a hexagonal spire. The tower of St Mary’s Church shows Norman work with Roman materials. The other public buildings are the grammar school, founded in 1547; the town-hall, formerly D’Arcy’s tower, built in the reign of Henry VI.; and the public hall. There are manufactures of crystal, glass and a fishery, and some shipping. On Osea Island, in the Blackwater estuary, there is a farm colony for the unemployed. A mile west of Maldon are remains of Beeleigh Abbey, a Premonstratensian foundation of the 12th century. They consist of the chapter-house and another chamber, and are of fine Early English work. The borough is under a mayor, 4 aldermen and 12 councillors. Area, 3028 acres.

At Maldon (Maldune, Maldune, Mealden or Meadon) a palaeolithic, neolithic and Roman remains that have been found seem to indicate an early settlement. It is not, however, an important Roman site. An earthwork, of which traces exist, may be Saxon or Danish. The Anglo-Saxon Chronicle relates that Edward the Elder established a “burh” there about 921, and that Ealdorman Brihtnoth was killed there by the Danes in 991. The position of Maldon may have given it some commercial importance, but the fortress is the point emphasized by the Chronicle. Maldon remained a royal town up to the reign of Henry III., when it was ceded to the Hales. Later in the 12th century, Henry II. granted the burgesses their first charter, probably in 1155, giving them the land of the borough and suburb with sac and soc and other judicial rights, also freedom from county and forest jurisdiction, danelag, scutage, tallage and all talls, by the service of one ship a year for forty days. This charter was confirmed by Edward I. in 1290, by Edward III. in 1344, and by Richard II. in 1378. In 1403 the bishop of London granted further judicial and financial rights, and Henry V. confirmed the charters in 1417, Henry VI. in 1443, and Henry VIII. in 1525. Maldon was incorporated by Philip and Mary in 1554, and received confirmatory charters from Elizabeth in 1563 and 1592, from Charles I. in 1631, Charles II. and James II. In 1768 the incorporation charter was regranted, with modifications in 1810.

MALEBRANCHE, NICOLAS (1638-1715), French philosopher of the Cartesian school, the youngest child of Nicolas
MALER KOTLA—MALESHERBES

Malerbranche, secretary to Louis XIII., and Catherine de Lauzon, sister of a vicerey of Canada, was born at Paris on the 6th of August 1638. Deformed and constitutionally feeble, he received his elementary education from a tutor, and left home only when sufficiently advanced to enter upon a course of philosophy at the Collège de la Marche, and subsequently to study theology at the Sorbonne. He had resolved to take holy orders, but his studious disposition led him to decline a stall in Notre Dame, and in 1660 he joined the congregation of the Oratory. He was first advised by Père Lecointe to devote himself to ecclesiastical history, and laboriously studied Eusebius, Socrates, Sozomen and Theodoret, but “the facts refused to arrange themselves in his mind, and mutually effaced one another.” Richard Simon undertook to teach him Hebrew and Biblical criticism with no better success. At last in 1664 he chanced to read Descartes’s Traité de l’homme (de homine), which moved him so deeply that (it is said) he was repeatedly compelled by palpitations of the heart to lay aside his reading. Malebranche was from that hour consecrated to philosophy, and after ten years’ study of the works of Descartes he produced the famous De la recherche de la vérité, followed at intervals by other works, both speculative and controversial. Like most of the great metaphysicians of the 17th century, Malebranche interested himself also in questions of mathematics and natural philosophy, and in 1699 was admitted an honorary member of the Academy of Sciences. During his later years his society was much courted, and he received many visits from foreigners of distinction. He died on the 13th of October 1715; his end was said to have been hastened by a metaphysical argument into which he had been drawn in the course of an interview with Bishop Berkeley. For a critical account of Malebranche’s place in the history of philosophy, see CARTESIANISM.

Works.—De La recherche de la vérité (1674; 6th ed., 1712; ed. Bossiére, 1850; Latin trans. by J. Lenfant at Geneva in 1685; English trans. by R. Sault, 1684; and T. Taylor, 1694, 1712); Conversations chrétienne (1677, 1678; frequently; Eng. trans., London, 1685); Méditations chretiennes et métaphysiques (1683); Traité de morale (1684; separate ed. by H. Joly, 1882; Eng. trans. by Sir J. Shipton, 1699); several polemical works against Arnauld (1684–1688; Extracts from the métophysique et sur la religion (1688); Traité de l’amour de Dieu (1697); Entretiens d’un philosophe chrétien et d’un philosophe chinois sur l’existence et la nature de Dieu (1708); Réflexions sur la prémortime (1713)."

A convenient edition of his works in two volumes, with an introduction, was published by Jules Simon in 1842. A full account by Mrs Norman Smith of his theory of vision, in which he unquestionably worked, is admirably presented. Some of the most important parts of Malebranche’s work of Berkeley, will be found in the British Journal of Psychology (Jan. 1905). For recent criticism see H. Joly, in the series Les Grands philosophes (Paris, 1901); L. Ollé-Laprune, La Philosophie de Malebranche (1879); M. Novaro, Die Philosophie des Nicolas Malebranche (1893).

Malerota, a native state of India, within the Punjab. It ranks as one of the Cis-Sutlej states, which came under British influence in 1809. The territory, south of Ludhiana, area, 10,638 square miles, showing an increase of 0.8% in the decade. Estimated gross revenue, £40,100. The military force numbers 880 men; and there is no tribute. The town Malerota is 30 m. S. of Ludhiana; pop. (1901), 21,122. The nawab or chief is of Afghan descent; his family originally came from Kabul, and occupied positions of trust in Sherind under the Mogul emperors. They gradually became independent as the Mogul Empire sank into decay in the course of the 18th century. In General Lake’s campaign against Holkar in 1803 the nawab of Malerota sided with the British. After the subjugation and flight of Holkar, the English government succeeded to the power of the Maharrats in the districts between the Sutlej and the Jumna; and in 1809 its protection was formally extended to Malerota, as to the other Cis-Sutlej states, against the formidable encroachments of Ranjit Singh. In the campaigns of 1806, 1807 and 1808 Ranjit Singh had made considerable conquests across the Sutlej; in 1808 he marched on Malerota and demanded a ransom of £60,000 from the nawab. This led to the interference of the British, who addressed an ultimatum to Ranjit Singh, declaring the Cis-Sutlej states to be under British protection. Finally the raja of Lahore submitted, and the nawab was reinstated in February 1809. Owing to the mental incapacity of nawab Ibrahim Ali Khan, the state was administered in recent years for some time by the chief of Loharu; but his son, Ahmed Ali Khan, was made regent in February 1905.

See Maler Kotal State Gazetteer (Lahore, 1908).

MALESHERBES, CHRÉTIEN GUILLAUME DE LAMOIGNON DE (1721–1794), commonly known as Lamoignon-Malesherbes, French statesman, minister, and afterwards counsel for the defence of Louis XVI., came of a famous legal family. He was born at Paris on the 6th of December 1721, and was educated for the legal profession. The young lawyer soon proved his intellectual capacity, when he was appointed president of the cour des aides in the parlement of Paris in 1750 on the promotion of his father, Guillaume de Lamoignon, to be chancellor. One of the characteristic duties was to control the press, and this duty was entrusted to Malesherbes by his father during his eighteen years of office, and brought him into connexion with the public more than his judicial functions. To carry it out efficiently he kept in communication with the literary leaders of Paris, and especially with Diderot, and Grimm even goes so far as to say that “without the assistance of Malesherbes the Encyclopédie would probably never have been published.” In 1771 he was called upon to mix in politics; the parlements of France had been dissolved, and a new method of administering justice devised by Maupois, which was in itself commendable as tending to the better and quicker administration of justice, but pernicious as exhibiting a tendency to over-centralisation, and as abolishing the hereditary “nobility of the robe,” which, with all its faults, had from its nature preserved some independence, and been a check on the royal power. Malesherbes presented a strong remonstrance against the new system, and was at once banished to his country seat at St Lucie, to be recalled, however, with the old parlement on the accession of Louis XVI., and to be made minister of the maison du roi in 1775. He only held office nine months, during which, however, he directed his attention to the police of the kingdom, which came under his department, and did much to check the odious practice of issuing lettres de cachet. The protest of the cour des aides in 1775 is one of the most important documents of the old régime in France. It gives a complete survey of the corrupt and inefficient administration, and presented the king with most outspoken criticism. On retiring from the ministry with Turgot in 1776, he betook himself entirely to a happy country and domestic life and travelled through Switzerland, Germany and Holland. An essay on Protestant marriages (1787) did much to procure for them the civil recognition in France. He had always been an enthusiastic botanist; his avenue at St Lucie was world famous; he had written against Buffon in behalf of the botanists whom Buffon maltreated, and had been elected a member of the Académie des sciences as far back as 1759. He was now elected a member of the Académie françoise, and everything seemed to promise a quiet and peaceful old age spent in the bosom of his family and occupied with scientific and literary pursuits, when the king in his difficulties wished for the support of his name, and summoned him back to the ministry in 1787. Lamoignon-Malesherbes held office but a short time, but returned to his country life this time with a feeling of insecurity and disquiet, and, as the troubles increased, retired to Switzerland. Nevertheless, in December 1792, in spite of the fair excuse his old age and long retirement would have given him, he voluntarily left his asylum and undertook with Tronchet and Desèze the defence of the king before the Convention, and it was his painful task to break the news of his condemnation to the king. After this effort he returned once more to the country, but in December 1793 he was arrested with his daughter, his son-in-law M. de Rosambô, and his grandchildren, and on the 23rd of April 1794 he was guillotined, after having seen all the world executed before his eyes for their relationship to him. Malesherbes is one of the
sweetest characters of the 18th century; though no man of action, hardly a man of the world, by his charity and unfeigned goodness he became one of the most popular men in France, and it was an act of true self-devotion in him to sacrifice himself for a king who had done little or nothing for him.

There are in print several scientific works of Malesherbes of varying value, of which the most interesting is his Observations sur Buffon et Daubenton, written when he was very young, and published with a notice by Abbele in 1798. There exist also his Mémoire pour Louis XVI, his Mémoire sur la liberté de la presse (published 1809) and extracts from his remonstrances, published as Œuvres choisies de Malesherbes in 1809. For his life should be read the Notice historique (3rd ed., 1860) of Dubois, the Éloge historique (1805) of Coste, and the Nouvel Essai sur la vie de M. de Malesherbes (2 vols., 1818), by F. A. de Boissy d'Anglas. There are also many éloges on him in print, of which the best-known is that of M. Dupin, which was delivered at the Academy in 1841, and was reviewed with much light on Malesherbes's control of the press by Sainte-Beuve in the 2nd volume of the Coursier du lundi. The protest of the cour des aides has been published with translation by G. Robinson in the Translations and Reprints of the University of Pennsylvania (1904). For his defence of Louis XVI see Marquis de Beaucourt, Capitales et derniers moments de Louis XVI (2 vols., 1892, Soc. d'hist. contemp.), and A. Tuetey, Répertoire général des sources manuscrites de l'hist. de Paris pendant la Reg. sr., vol. viii. (1908).

MALET, LUCAS, the pen-name of Mary St Leger Harrison (1852- ), English novelist. She was the eldest daughter of Charles Kingsley, and was born at Eversley on the 4th of June 1852. She studied at the Slade school and at University College, London, and married in 1876 William Harrison, rector of Clovelly. After her husband's death in 1887 she eventually settled in London. She had already written several books—Mrs Lorimer (1882), Colonel Endersby's Halt (1885), Little Peter (1887), A Counsel of Perfection (1888)—when she published her powerful story, The Persecution of Sim (1891), which attracted great attention. Her History of Sir Radical Cashmire (1901) had an even greater success. Her other novels include The Carissima (1896), The Gateless Barrier (1900), On the Far Horizon (1906).

MALHERBE, FRANÇOIS DE (1555-1628), French poet, critic and translator, was born at Caen in 1555. His family was of some position, though it seems not to have been able to establish to the satisfaction of heralds the claims which it made to nobility older than the 16th century. The poet was the eldest son of another François de Malherbe, conseiller du roi in the magistracy of Caen. He himself was elaborately educated at Caen, at Paris, at Heidelberg and at Basel. At the age of twenty-one, preferring arms to the gown, he entered the household of Henri d'Angouleme, grand prior of France, the natural son of Henry II. He served this prince as secretary in Provence, and afterwards there in 1581. It seems that he wrote verses at this period, but, to judge from a quotation of Tallemant des Réaux, they must have been very bad ones. His patron died when Malherbe was on a visit in his native province, and for a time he had no particular employment, though by some servile verses he obtained a considerable gift of money from Henry III., whom he afterwards libelled. He lived partly in Provence and partly in Normandy for many years after this event; but very little is known of his life during this period. His Larmes de Saint Pierre, imitated from Luigi Tansillo, appeared in 1587.

It was in the year parting the two centuries (1600) that he presented to Marie de' Medici an ode of welcome, the first of his remarkable poems. But four or five years more passed before his fortune, which had hitherto been indifferent, turned. He was presented by his countryman, the Cardinal Du Perron, to Henry IV.; and, though that economical prince did not at first show any great eagerness to entertain the poet, he was at last summoned to court and endowed after one fashion or another. It is said that the pension promised him was not paid till the next reign. His father died in 1606, and he came into his inheritance. From this time forward he lived at court, corresponding affectionately with his wife, but seeing her only twice in some twenty years. His old age was saddened by a great misfortune. His son, Marc Antoine, a young man of promise, fell in a duel in 1626. His father used his utmost influence to have the guilty parties (for more than one were concerned, and there are grounds for thinking that it was not a fair duel) brought to justice. But he died before the suit was decided (it is said in consequence of disease caught at the camp of La Rochelle, whither he had gone to petition the king), in Paris, on the 16th of October, 1628, at the age of seventy-three.

The personal character of Malherbe was far from amiable, but he exercised, or at least indicated the exercise of, a great and enduring effect upon French literature, though by no means a wholly beneficial one. The lines of Boileau beginning Enfin Malherbe vint are rendered only partially applicable by the extraordinary ignorance of older French poetry which distinguished that peremptory critic. But the good as well as bad side of Malherbe's theory and practice is excellently described by his contemporary and superior Regnier, who was animated against him, not merely by reason of his own devotion to Ronsard but because of Malherbe's discourtesy towards Regnier's uncle P. Desportes, whom the Norman poet had at first distinctly copied. These are the lines:

"Cependant leur savoir ne s'étend nullement
Qu'à régratter un mot douteux au jugement
Prendre garde qu'un gui ne heurte une diphonghe,
Epier si des vers la rime est brève ou longue,
Bosse si la voix n'est plus la voyelle à l'autre s'unissant.
Ne rend point à l'oreille un vers trop languissant.

C'est proser de la rime et rimer de la prose."

This is perfectly true, and from the time of Malherbe dates that great and deplorable falling off of French poetry in its more poetic qualities, which was not made good till 1830. Nevertheless the critical and restraining tendency of Malherbe was not ill in place after the luxuriant importation and innovation of the Pléiade; and if he had confined himself to preaching greater purity and greater simplicity and purity in vocabulary and versification, instead of superciliously striking his pen through the great works of his predecessors, he would have deserved wholly well. As it was, his reforms helped to elaborate the kind of verse necessary for the classical tragedy, and that is the most that can be said for him. His own poetical work is scanty in amount, and for the most part frigid and devoid of inspiration. The beautiful Consolation à Duperier, in which occurs the famous line—

"Et, rose, elle a vécu ce que vivent les roses—
the odes to Marie de' Medici and to Louis XIII., and a few other pieces comprise all that is really worth remembering of him. His prose work is much more abundant, not less remarkable for care as to style and expression, and of greater positive value. It consists of some translations of Livy and Seneca, and of a very large number of interesting and admirably written letters, many of which are addressed to Peiresc, the man of science of whom Gassendi has left a delightful Latin life. It contains also the most curious commentary on Desportes, in which Malherbe's minute and carping style of verbal criticism is displayed on the greatest scale.

The chief authorities for the biography of Malherbe are the Vie de Malherbe by his friend and pupil Racan, and the long Historiette which Tallemant des Réaux has devoted to him. The standard edition is the admirable one of Ludovic Lalanne (5 vols., Paris, 1862-1869). Of the poems one has excellent and handsome little issue in the Nouvelle collection Janet (Paris, 1874). Of modern works devoted to him, La Doctrine de Malherbe, by G. Brunot (1891), is not only the most important but a work altogether capital in regard to the language of literature. Others are A. Gasté, La Jeunesse de Malherbe (1890); V. Bourrienne, Points obscurs dans la vie normande de Malherbe (1895); and the duc de Broglie's " Malherbe en Les Grandes érudits français. On his position in French and general critical history, G. Stainsbury's History of Criticism, vol. ii., may be consulted. (G. S.)

MALIBRAN, MARIE FÉLICITÉ (1808-1836), operatic singer, daughter of Manuel Garcia, was born in Paris on the 24th of March 1808. Her father was then a member of the company of the Théâtre des Italiens, and she accompanied him to Italy and London. She possessed a soprano voice of unusual beauty and
MALIC ACID—MALINES 489

phenomenal compass, which was carefully cultivated by her father. She was only seventeen when, in consequence of an indisposition of Madame Pana, she was suddenly asked to take her place in The Barber of Seville at C, and forthwith engaged for the remaining six weeks of the season, and then followed her father to New York, where she appeared in Othello, The Barber of Seville, Don Juan, Romeo and Juliet, Tancred. Her gifts as an actress were on a par with her magnificent voice, and her gaiety made her irresistible in light opera, although her great triumphs were obtained chiefly in tragic parts. She married a French banker of New York, named Malibran, who was much older than herself. The marriage was an unhappy one, and Mme Malibran returned alone to Europe in 1828, when she began the series of representations at the Théâtre des Italiens, which excited an enthusiasm in Paris only exceeded by the reception she received in the principal towns of Italy. She was formally divorced from Malibran in 1835, and married the Belgian violinist, Charles de Beriot; but she died of fever on the 23rd of September 1836.

See Memoirs of Mme Malibran by the comtesse de Merlin and other intimate friends, with a selection from her correspondence (2 vols., 1840); and M. Teico, La Malibran, d’après des documents intimes, in Sammeltedten internationalen Musik-Gesellschaft (Leipzig, 1896).

MALIC ACID (Hydroxyethylene Succinic Acid), C6H10O5, an organic acid found abundantly in the juices of many plants, particularly in mountain-ash berries, in unripe apples and in grape-stalks. The solid potassium salt is also found in the leaves and stalks of rhubarb. Since the acid contains an asymmetric carbon atom, it can exist in three forms, a dextro-rotatory, a laevorotatory and an inactive form; the acid obtained in the various synthetic processes is the inactive form. It may be prepared by heating racemic acid (see Tartaric Acid) with fuming hydrobromic acid; by heating fumaric acid (q.v.) with water at 150–200°C.; by the action of nitrous acid on inactive aspartic acid; and by the action of moist silver oxide on monobromosuccinic acid. It forms deliquescent crystals, which are readily soluble in alcohol and melt at 100°C. When heated for some time at 130°C. it yields fumaric acid (q.v.), and on rapid heating at 180°C. gives maleic anhydride and fumaric acid. It yields coumarins when warmed with sulphuric acid and phenols (H. v. Pechmann, Ber., 1884, 17, 926, 1649 et seq.). Potassium bichromate oxidizes it to maleic acid; nitric acid oxidizes it to oxalic acid; and hydrobromic acid reduces it to succinic acid. The inactive variety may be split into the component active forms by means of its cinchonine salt (G. J. W. Bremer, Ber., 1880, 13, 352).

MALIGNANT (Lat. malignus, evil-disposed, from maligenus), wicked, of a malicious or willfully evil disposition. The word was early applied by the Protestants to the Romanists, with an allusion to the “congregation of evil doers” (Vulgata Ecclesiæ malignum) of Psalm xxvi. 5. In English history, during the Great Rebellion, the name was given to the Royalists by the Parliamentary party. In the Great Remonstrance of 1641 occur the words “the malignant partie, whereof the Archbishop (Laud) and the earl of Strafford being heads.” The name throughout the period had special reference to the religious differences between the parties. In medical science, the term “malignant” is applied to a particularly virulent or dangerous form which a disease may take, or to a tumour or growth of rapid growth, extension to the lymphatic glands, and recurrence after operation.

MALIK IBN ANAS (c. 718–795), the founder of the Malikite school of canon law, was born at Medina about A.D. 718: the precise date is not certain. He studied and passed his life there, and came to be regarded as the greatest local authority in theology and law. (For his legal system and its history see MAHOMMEDAN LAW.) His life was one of extreme honour and dignity, but uneventful, being given to study, lecturing on law and acting as mufti and judge. Only two episodes stand out in his biography. When Mahommed ibn 'Abdallah, the 'Aliid, rose in A.D. 762 at Medina against the 'Abbasids, Malik gave a false, or legal opinion, that the oath of allegiance to the 'Abbâsids was invalid, as extorted by force. For this independence he was severely scourged by the 'Abbâsîd governor, who, apparently, did not dare to go beyond scourging with a rod. That episode stands with the people. The second episode gave awful proof of independence. In 795 Harun al-Rashid made the pilgrimage, came with two of his sons to Medina, and sat at the feet of Malik as he lectured in the mosque. The story, legendary or historical, adds that Malik had refused to go to the caliph, saying that it was for the student to come to his teacher. Late in life he seems to have turned to asceticism and contemplation. It is said that he retired from all active, public life and even neglected plain, public duties, replying to reproaches, “Not every one can speak in his own excuse” (Ibn Qutabi, Ma 'arif, 250). He is also said to have come among the early ascetic Sufis (cf. Fihrist, 183). He died in Medina, A.D. 795.

For a description of his principal book, the Mawaffaq, see Goldzieher’s Muhammadanische Studien, ii. 213 sqq. He wrote also a Koran commentary, now apparently lost, and a hortatory epistle to Harun al-Rashid, entitled, Martha. See fragments of Ibn Malik, ii. 545 sqq.; van Kremer, Geschichtsere, i. 477 sqq.; Brockelmann, Gesch. der arab. Lit., i. 175 sqq.; Macdonald, Muslim Theology, &c., 99 sqq. and index; Fihrist, 198 seq.; Nawawi, 530 sqq.

(D. B. M.)

MALINES (Flemish, Mechelen, called in the middle ages by the Latin name Mechlinia, whence the spelling Mechlin), an ancient and important city of Belgium, and the seat since 1559 of the only archbishopric in that country. Pop. (1904), 58,101. The name Malines is supposed to be derived from maris linea, and to indicate that originally the sea came up to it. It is now situated on the Dyle, and is in the province of Antwerp, lying about half-way between Antwerp and Brussels. The chief importance of Malines is derived from the fact that it is in a sense the religious capital of Belgium—the archbishop being the primate of the Catholic Church in that country. The archbishop’s palace is in a picturesque situation, and dates from the creation of the dignity. The principal building in the city is the exceedingly fine cathedral dedicated to St Rombaut. This cathedral was begun in the 12th and finished early in the 14th century, and although modified in the 15th after a fire, it remains one of the most remarkable specimens of Gothic architecture in Europe. The massive tower of over 300 ft., which is described as unfinished because the original intention was to carry it to 500 ft., is its most striking external feature. The people of Malines gained in the old distich—“gaudet Mechlinia stultus”—“the reputation of being ‘fools,’ because one of the citizens on seeing the moon through the dormer windows of St Rombaut called out that the place was on fire, and his fellow-citizens, following his example, endeavoured to put out the conflagration until they realized the truth. The cathedral contains a fine altar-piece by Van Dyck, and the pulpit is carved oak of the 17th century. Another place that of Margaret of Austria, regent for Charles V., which has been carefully preserved and now used as a court of justice. In the church of Notre Dame (16th century) is Rubens’ masterpiece “the miraculous draught of fishes,” and in that of St John is a fine triptych by the same master. Malines, although no longer famous for its lace, carries on a large trade in linen, needles, furniture and oil, while as a junction for the line from Ghent to Louvain and Liège, as well as for that from Antwerp to Brussels and the south, its station is one of the busiest in Belgium, and this fact has contributed to the general prosperity of the city.

The lordship of Malines was conferred as a separate fief by Pippin the Short on his kinsman Count Adon in 754. In the 9th century Charles the Bald bestowed the fief on the bishop of Liège, and after being shared between Brabant and Flanders it passed into the hands of Philip the Bold, founder of the house of Burgundy, in 1384. During the religious troubles of the 16th century Malines suffered greatly, and in 1572 it was sacked by Alva’s troops during three days. In the wars of the 17th and 18th centuries it was besieged many times and captured by the French, Dutch and English on several occasions. The French finally removed the fortifications in 1804, since which year it has been an open town.
Mallanwan, a town in Haroi district, the United Provinces, India. Pop. (1901), 11,158. Under native rule the town possessed considerable political importance, and upon the British annexation of Oudh it was selected as the headquarters of the district, but was abandoned in favour of Haroi after the Mutiny.

Salt petre and brass utensils are manufactured.

Mallarmé, François René Auguste (1842-1898), French poet and theorist, was born at Nancy on the 25th of February 1842. He was brought up in his father's profession, and was appointed procureur-syndic of the district of Pont-A Mousson. During the Revolution he was elected by the department of Meurthe deputy to the Legislative Assembly and the Convention, where he attached himself to the Mountain and voted for the death of Louis XVI. He was elected president of the Convention on the 5th of May 1793, and by his weakness during the crisis of the following day contributed much to the success of the insurrection against the Girondists. He took an active part in the l'eté- en-mas, and in November 1793 was given the task of establishing the revolutionary government in the departments of Meuse and Moselle, where he gained an unenviable notoriety by ordering the execution of the sentence of death decreed by the revolutionary tribunal on some young girls at Verdun who had offered flowers to the Prussians when they entered the town. After the fall of Robespierre he joined the group of "Thermidorians" and was sent on mission to the south of France, where he closed the Jacobin club at Toulouse and set free a number of imprisoned "suspects." On the 1st of June 1795 he was denounced and arrested, but was soon set at liberty. In 1796 he was appointed by the Directory commissioner for the organization of the departments of Dyle and Mont-Tonnere. Under the empire he was receiver of the droits réunis at Nancy, and lost his money in 1814 in raising a levy of volunteers. Appointed sub-prefect of Avennes during the Hundred Days, he was imprisoned by the Prussians in revenge for the death of the maidens of Verdun, and lived in exile during the Restoration. He returned to France after the revolution of 1830, and died at Richemont (Seine-Inférieure) on the 25th of July 1835.

Mallarmé, Stéphane (1842-1898), French poet and theorist, was born at Paris, on the 18th of March 1842. His life was simple and without event. His small income as professor of English in a French college was sufficient for his needs, and, with his wife and daughter, he divided the year between a fourth-floor flat in Paris and a cottage on the banks of the Seine. His Tuesday evening receptions, which did so much to form the thought of the more interesting of the younger French men of letters, were almost as important a part of his career as the carefully elaborated books which he produced at long intervals.

L'Après-midi d'un faune (1876) and other fragments of his verse and prose had been known to a few people long before the publication of the Poésies complètes of 1887, in a facsimile of his clear and elegant handwriting, and of the Pages of 1891 and the Vers et prose of 1893. His remarkable translation of poems of Poe appeared in 1888, "The Raven" having been published as early as 1875, with illustrations by Manet. Divagations, his own final edition of his prose, was published in 1897, and a more or less complete edition of the Poésies, posthumously, in 1899. He died at Valvins, Fontainebleau, on the 9th of September 1898. All his life Mallarmé was in search of a new aesthetics, and his discoveries by the way were often admirable. But he was too critical ever to create freely, and too limited ever to create abundantly. His great achievement remains unfinished, and all that remains is not of equal value. There are a few poems and a few pieces of imaginative prose which have the haunting quality of Gustave Moreau's pictures, with the same jewelled magnificence, mysterious and yet definite. His later work became more and more obscure, as he seemed to himself to have abolished limit after limit which holds back speech from the expression of the absolute. Finally, he abandoned punctuation in verse, and invented a new punctuation, along with a new construction, for prose. Patience in the study of so difficult an author has its reward. No one in our time has vindicated with more pride the self-sufficiency of the artist in his struggle with the material world. To those who knew him only by his writings his conversation was startling in its clearness; it was always, like all his work, at the service of a few dignified and misunderstood ideas.

Symons, The Symbolist Movement in Literature (1900). A comprehensive bibliography is in the Poètes d'aujourd'hui (1900-1900, 11th ed., 1909) of M. A. van Bever and P. Lautaud. (A. S.)

Malocco, a province of southern Chile, once a part of the Indian territory of Araucania (q.v.), lying between the provinces of Bio-Bio on the N. and Cautin on the S. and Arauco on the W. Area, 2973 sq. m. Pop. (1895), 85,052. It belongs to the rainy, forested region of southern Chile, and is thinly populated, a considerable part of its population being Araucanian Indians, who occupy districts in the Andean foothills. Gold placer mining has attracted some attention, but the output is small. The principal industries are cattle and wheat raising and timber-cutting. The capital is Angol (pop., 7056 in 1895; estimated at 7638 in 1902), a small town in the northern part of the province, on the Malleco river, and a station on the Traiguén branch of the state railway. Traiguén (pop., 5732 in 1895; estimated at 7099 in 1902) in the southern part of the province is the second town in importance, and Victoria (pop., 6586 in 1895; estimated at 10,002 in 1902), about 20 m. E. of the last-named town, was for a time the terminal station of the main line of the railway.

Mallemuck, from the German rendering of the Dutch Mallemugge (which originally meant small flies or midges that madly whirl round a light), a name given by the early Dutch Arctic voyagers to the Fulmar (q.v.), of which the English form is nowadays most commonly applied by our sailors to the smaller albatrosses, of about the size of a goose, met with in the Southern Ocean—corrupted into "molly mawk," or "mollumawk." A number of species have been identified.

Diomedes irrorata of West Peru is sooty-brown with white mottlings and a white head; D. migrata of the North Pacific is similar in colour but with white only near the eye and at the base of the tail and bill; D. immutabilis of Japan is darker but has a white head. D. melanephyris of the southern oceans has been found in summer both in California, in England, and as far north as the Faeroes. According to J. Gould the latter is the commonest species of albatross inhabiting the Southern Ocean, and its gregarious habits and familiar disposition make it well known to every voyager to or around the South Island, for it is equally common in the Atlantic as well as the Pacific. The back, wings and tail are of a blackish-grey but all the rest of the plumage is white, except a dusky superciliary streak, whence its name of black-browed albatross, as also its scientific epithet, are taken. The bill of the adult is of an ochreous-yellow, while that of the young is dark. This species breeds on the Falkland Islands. D. bulleri of the New Zealand seas is greyish-brown, while white underparts and rump and ash head. Diomedea (or Thalassogeron) culminata and chlororhyncha of the southern seas, D. (or T.) cauta of Tasmania, salveini of New Zealand and layardi of the Cape resemble D. bulleri, but have a strip of naked skin between the plates of the maxilla towards its base. H. N. Moseley (Notes of a Naturalist, 130) describes D. culminata as making a cylindrical nest of grass, seagreen clays, with a shallow basin atop and an overhanging rim—the whole being about 14 in. in diameter and 10 in. in height. The bird lays a single white egg, which is held in a sort of pouch, formed by the skin of the abdomen, while she is incubating. The feet of D. bulleri are red, of D. chlororhyncha flesh-coloured, of the others yellow. (A. N.)

Malleson, George Bruce (1825-1898), Indian officer and author, was born at Wimbledon, on the 8th of May 1825. Educated at Winchester, he obtained a cadetship in the Bengal infantry in 1842, and served through the second Burmese War. His subsequent appointments were in the civil line, the last being that of guardian to the young maharaja of Mysore. He retired
Mallet, D.—Mallet du Pan

with the rank of colonel in 1872, having been created C.S.I. in 1872. He died at Kensington on the 1st of March 1898. He was a voluminous writer, his first work to attract attention being the famous "Red Pamphlet," published at Calcutta in 1857, when the Mutiny was at its height. He continued, and considerably rewrote the History of the Indian Mutiny (6 vols., 1878-1886), which was begun but left unfinished by Sir John Kaye. Among his other books the most valuable are History of the French in India (2nd ed., 1853) and The Decisive Battles of India (3rd ed., 1888).

**Mallet (or Malloch), David (1705-1765),** Scottish poet and dramatist, the son of a Perthshire farmer, was born in that county, probably in 1705. In 1727 he went to the high school at Edinburgh, and some three years later to the university, where he made the friendship of James Thomson, author of The Seasons. As early as 1720 he began to publish short poems in the manner of the period, a number of which appeared during the next few years in collections such as the Edinburgh Miscellanies and Allan Ramsay's Tea Table Miscellany, in which his ballad "William and Margaret" was published in 1724. For some years from 1725 he was private tutor to the duke of Montrose's sons, with whom he travelled on the Continent in 1727. His real name was Malloch; but this he changed to Mallet in 1724. In 1733 he took the M.A. degree at Oxford. He had already made the friendship of Pope, whose vanity he flattered in a poem on Verbal Criticism, in 1733; and through Pope he became acquainted with Bolingbroke and other Tory politicians, especially those attached to the party of the prince of Wales, who in 1742 appointed Mallet to be his paid secretary. After Pope's death, in 1744, Mallet, at the instigation of Bolingbroke and forgetful of past favours and friendship, vilified the poet's memory, thereby incurring the resentment of Pope's friends. For his services as a party pamphleteer, in which character he published an attack on Admiral Byng, Mallet received from Lord Bute a lucrative sinecure in 1746. He died on the 21st of April 1765. Mallet was a small man, in his younger days something of a dandy and inordinately vain. He was twice married; by his first wife he had a daughter, Dorothy, who married the Marquis of Huntingdon; by his second wife, a Genoese gentleman, and the author of several poems and plays, notably Almeida, produced by Garrick at Drury Lane in 1771.

Mallet's own works included several plays, some of which were produced by Garrick, who was Mallet's personal friend. Eurydice, a tragedy, with prologue and epilogue by Aaron Hill, was produced at Drury Lane in 1731; Mustapha, also a tragedy, had considerable success at the same theatre in 1739; in 1740, in collaboration with Thomson, he produced the masque Alfred, of which he published a new version in 1751, after Thomson's death, claiming it to be almost entirely his own work. This masque is notable as containing the well-known patriotic song, "Rule Britannia," the authorship of which has been attributed to Mallet, although he allowed it to appear without protest in his lifetime with Thomson's name attached. His other writings include Poems on Several Occasions (1743); A Pygmalion and Theodora, or the Harim (1747); another volume of Poems (1762).

In 1790 a collected edition of Mallet's Works, previously published in three volumes, and in 1797 his Ballads and Songs were edited by F. Dinsdale with notes, and a biographical memoir of the author.

**Mallet, Paul Henri** (1730-1807), Swiss writer, was born on the 20th of August 1739, in Geneva. After having been educated there, he became tutor in the family of the count of Calenberg in Saxony. In 1752 he was appointed professor of belles lettres to the academy at Copenhagen. He was naturally attracted to the study of the ancient literature and history of his adopted country, and in 1755 he published the first fruits of his researches, under the title Introduction à l'histoire du Danemark ou l'on traite de la religion, des mœurs, des lois, et des usages des anciens Danois. A second part, more particularly relating to the ancient literature of the country, Monuments de la mythologie et de la poësie des Celtes, et particulièrement des anciens Scandinaves, was issued in 1756, and was also translated into Danish. A translation into English, with notes and preface, by Bishop Percy, was issued in 1770 under the title of Northern Antiquities (republished with additions in 1847). The book had a wide circulation, and attracted much attention on account of its being the first (though a very defective) translation into French of the Edda. The king of Denmark showed his appreciation by choosing Mallet to be preceptor of the crown prince. In 1760 he returned to Geneva, and became professor of history in his native city. While there he was requested by the czarina to undertake the education of the heir-apparent of Russia (afterwards the czar Paul I.), but declined the honour. An invitation more congenial to his tastes led to his accompanying Lord Mountstuart in his travels through Italy and thence to England, where he was presented at court and commissioned to write the history of the house of Brunswick. He had previously received a similar commission from the landgrave of Hesse-Cassel for the preparation of a history of the house of Hesse, and both works were completed in 1785. The quietude of a literary life was rudely broken by the shock of the Revolution, to which he was openly hostile. His leanings to the unpopular side were so obnoxious to his fellow-citizens that he was obliged to quit his native country in 1792, and remained in exile till 1801. He died at Genoa, on the 8th of October 1803.

A memoir of his life and writings, by Siamonde, was published at Geneva in 1807. Besides the Introduction to the History of Denmark, his principal works are: Histoire du Danemark (5 vols., Copenhagen, 1758-1777); Histoire de la maison de Hesse (4 vols., 1760-1785); Histoire de la maison de la Hanovre (6 vols., 1775-1791); Histoire de la maison et des états de Mecklenbourg (1795); Histoire des Suisses ou Helvétiens (4 vols., Geneva, 1803) (mainly an abridgment of J. von Müller's great history); Histoire de la ligue hanséatique (1805).

**Mallet, Robert** (1810-1881), Irish engineer, physicist and geologist, was born in Dublin, on the 3rd of June 1810. He was educated at Trinity College in that city, and graduated B.A. in 1830. Trained as an engineer, he was elected M.Inst.C.E. in 1842; he built in 1848-1849 the Fastnet Rock lighthouse, southwest of Cape Clear, and was engaged in other important works. Devoting much attention to pure science, he became especially distinguished for his researches on earthquakes, and from 1852-1858 he was engaged (with his son John William Mallet) in the preparation of his great work, The Earthquake Catalogue of the British Association (1858). In 1862 he published two volumes, dealing with the Great Neapolitan Earthquake of 1857 and The First Principles of Observational Seismology. He then brought forward evidence to show that the depth below the earth's surface, whence came the impulse of the Neapolitan earthquake, was about 8 or 9 geographical miles. One of his most important essays was that communicated to the Royal Society (Phil. Trans. cxliii. 147; 1874), entitled Volcanic Energy: An Attempt to develop its True Origin and Cosmical Relations. He sought to show that volcanic heat may be attributed to the effects of crushing, corrosion and other disturbances in the crust of the earth; the disturbances leading to the formation of lines of fracture, more or less vertical, down which water would find its way, and if the temperature generated be sufficient volcanic eruptions of steam or lava would follow. He was elected F.R.S. in 1854, and he was awarded the Wollaston medal by the Geological Society of London in 1877. He died at Clapham, London, on the 5th of November 1881.

**Mallet du Pan, Jacques** (1749-1800), French journalist, of an old Huguenot family, was born near Geneva in 1749, the son of a Protestant minister. He was educated at Geneva, and through the influence of Voltaire obtained a professorship at Cassel. He soon, however, resigned this post, and going to London joined H.S.N. Linguet in the production of his Annales politiques (1778-1780). During Linguet's imprisonment in the Bastille Mallet du Pan continued the Annales by himself (1781-1783); but Linguet presented this on his release, and Mallet du Pan changed the title of his own publication to Mémoires historiques (1783). From 1783 he incorporated this work with the Mercure de France in Paris, the political direction of which had been placed in his hands. On the outbreak of the French Revolution he sided with the Royalists, and was sent on a mission (1791-1792) by Louis XVI. to Frankfort to try and secure the
sympathy and intervention of the German princes. From Germany he travelled to Switzerland and from Switzerland to Brussels in the Royalist interest. He published a number of anti-revolutionary pamphlets, and a violent attack on Bonaparte and the Directory resulted in his being exiled in 1797 to Berne. In 1798 he came to London, where he founded the Mercure britannique. He died at Richmond, Surrey, on the 10th of May 1800, his widow being pensioned by the English government. Mallet du Pan has a place in history as a pioneer of modern political journalism. His son John Lewis Mallet (1775-1861) spent a useful life in the English civil service, becoming secretary of the Board of Audit; and J. L. Mallet's second son, Sir Louis Mallet (1823-1890) also entered the civil service in the Board of Trade and rose to be a distinguished economist and a member of the Council of India.

Mallet du Pan's Mémoires et correspondance was edited by A. Sayous (Paris, 1851). See Mallet du Pan and the French Revolution (1902), by Bernard Mallet, son of Sir Louis Mallet, author also of a biography of his father (1900).

**MALLING, EAST and WEST**, two populous villages in the Medway parliamentary division of Kent, England, respectively 5 and 6 m. W. by N. of Maidstone, with a station on the South-Eastern and Chatham railway. Pop. (1901), East Malling, 2,901; West Malling, 2,312. They are situated in a rich agricultural district on the western slope of the valley of the Medway, and East Malling has large paper mills. At West Malling are remains of Malling Abbey, a Benedictine nunnery founded in 1090 by Gundulf, bishop of Rochester. The remains, which are partly incorporated in a modern building, include the Norman west front of the church, the Early English cloisters, the chapter-house, gate-house (the chapel of which is restored to use), and other portions. About Addington near West Malling are considerable prehistoric remains, including mounds, single stones, stone circles and pits in the chalk hills; while at Leybourne are the gateway and other fragments of the castle held by the Leybourne family from the 12th to the 14th century.

**Mallock, William Hurrell** (1840-1900), English author, was born at Cockington Court, Devonshire. He was educated privately, and at Balliol College, Oxford. He won the Newdigate prize in 1872, and took a second class in the final classical schools in 1874. He attracted considerable attention by his satirical story *The New Republic* (2 vols., 1877), in which he introduced characters easily recognized as prominent living men, Mark Pattison, Matthew Arnold, W. K. Clifford and others. His keen logic and gift for acute exposition and criticism were displayed in later years both in fiction and in controversial works. In a series of books dealing with religious questions he insisted on dogma as the basis of religion and on the impossibility of founding religion on purely scientific data. In *Is Life Worth Living?* (1870) and *The New Paul and Virginia* (1878) he attacked Positivist doctrines, and in a volume on the intellectual position of the Church of England, *Doctrine and Doctrinal Disruption* (1900), he advocated the necessity of a strictly defined creed. Later volumes on similar topics were *Religion as a Credible Doctrine* (1903) and *The Reconstruction of Belief* (1905). He published several brilliant works on economics, directed against Radical and Socialist theories: *Social Equality* (1882), *Property and Progress* (1884), *Labour and the Popular Welfare* (1893), *Classes and Masses* (1896) and *Aristocracy and Evolution* (1898); and among his anti-socialist works should be classed his novel, *The Old Order Changes* (1886). His other novels include *A Romance of the Nineteenth Century* (1881), *A Human Document* (1892), *The Heart of Life* (1895) and *The Veil of the Temple* (1904). He published a volume of *Poems* in 1880, and in 1900 *Lucretius on Life and Death* in verse.

**MALLING**, a market town and watering place of Co. Cork, Ireland, on the Blackwater, 1445 m. S.W. from Dublin, and 21 N. from Cork by the Great Southern and Western railway. Pop. (1901), 4,542. It is a junction for lines westward to Killarney and Co. Kerry, and eastward to Lismore and Co. Waterford. The town owes its prosperity to its beautiful situation in a fine valley surrounded by mountains, and possesses a rapid mineral spring, considered efficacious in cases of general debility and for scrobutic and consumptive complaints. A spa-house with pump-room and baths was erected in 1828. The parish church dates from 1818, but there are remains of an earlier building adjoining it. There are manufactures of mineral water and condensed milk, corn-mills and tanneries. Mallow received a charter of incorporation from James I. Its name was originally Magh Allo, that is, Plain of the Allo (the old name used by Spenser for this part of the river), and the ford was defended by a castle, built by the Desmonds, the ruins of which remain. A bridge connects the town with the suburb of Ballydaheen. Mallow is a centre for the fine salmon fishing on the Blackwater. The climate is very mild. The town was a parliamentary borough till 1885. It is governed by an urban district council.

**MALLOW**, botanically *Malva*, the typical genus of the natural order Malvaceae, embracing about sixteen species of annual and perennial herbaceous plants, widely distributed throughout the northern hemisphere. The mallows possess the reniform one-celled anthers which specially characterize the *Malvaceae* (q.v.). The petals also are united by their base to the tube formed by the coalesced filaments of the stamens. The special characters which separate the genus *Malva* from others most nearly allied to it are the involucre, consisting of a row of three separate bracts attached to the lower part of the true calyx, and the numerous single-seeded carpels disposed in a circle around a central axis, from which they become detached when ripe. The flowers are...
mostly white or pinkish, never yellow, the leaves radiate-veined, and more or less lobed or cut. Three species are natives of Britain. The musk mallow (Malva moschata) is a perennial herb with five-partite, deeply-cut leaves, and large rose-coloured flowers clustered together at the ends of the branched stems, and is found growing along hedges and borders of fields, blossoming in July and August. It owes its name to a slight musky odour diffused by the plant in warm dry weather when it is kept in a confined situation. The round-leaved dwarf mallow (Malva rotundifolia) is a creeping perennial, growing in waste sandy places, with roundish serrate leaves and small pinkish-white flowers produced in the axils of the leaves from June to September. It is common throughout Europe and the north of Africa, extending to Western and northern Asia. The common mallow (Malva sylvestris), the mauve of the French, is an erect biennial or perennial plant with long-stalked roundish-angular serrate leaves, and conspicuous axillary reddish-purple flowers, blossoming from May to September. Like most plants of the order it abounds in mucilage, and hence forms a favourite domestic remedy for colds and sore throats. The aniline dye called mauve derives its name from its resemblance to the colour of this plant.

MALMEDY — MALMESBURY

which ended in the king of Prussia’s overthrowing the republican party in Holland, which was inclined to France, and re-establishing the prince of Orange. In recognition of his services to his country he was created Baron Malmedy of Malmedy (Sept. 1788), and permitted by the king of Prussia to bear the Prussian eagle on his arms, and by the prince of Orange to use his motto “Je maintiens.” He returned to England, and took an anxious interest in politics, which ended in his seceding from the Whig party with the duke of Portland in 1793; and in that year he was sent by Pitt, but in vain, to try to keep Prussia true to the first coalition against France. In 1794 he was sent to Brunswick to solicit the hand of the unfortunate Princess Caroline for the prince of Wales, to marry her as proxy, and conduct her to her husband in England. In 1796 and 1797 he was at Paris and Lille vainly negotiating with the French Directory. After 1797 he became partially deaf, and quitted diplomacy altogether; but for his long and eminent services he was in 1806 created earl of Malmedy, and Viscount Fitzharris, of Heron Court in the county of Hants. He now became a sort of political Nestor, consulted on foreign policy by successive foreign ministers, trusted by men of the most different ideas in political crises, and above all the confidant, and for a short time after Pitt’s death almost the political director, of Canning. Younger men were also wont to go to him for advice, and Lord Penzance particularly, who was his ward, was tenderly attached to him, and owed many of his ideas on foreign policy directly to his teaching. His later years were free from politics, and till his death on the 21st of November 1820 he lived very quietly and almost forgotten. As a statesman, Malmedy had an influence among his contemporaries which is scarcely to be understood from his writings, but which must have owed much to personal charm of manner and persuasiveness of tongue; as a diplomatist, he seems to have deserved his reputation, and shares with Macartney, Auckland and the Pitts — the credit of raising diplomacy from a profession in which only great nobles won the principal recognition — opening the path of honour to ability. He was succeeded as second earl by his son James Edward (1778–1841), under-secretary for foreign affairs under Canning; from whom the title passed to James Howard, 3rd earl of Malmsbury (1824–1901).

MALMEDY did not publish anything himself, except an account of the Dutch revolution, and an edition of his father’s works, but his important Diaries (1844) and Letters (1870) were edited by his grandson.

MALMESBURY, JAMES HOWARD HARRIS, 3rd EARL OF (1807–1889), English statesman, son of the 2nd earl, was born on the 25th of March 1807, and educated at Eton and Oriel College, Oxford. He led a life of travel for several years, making acquaintance with famous people; and in 1841 he had only just been elected to the House of Commons as a Conservative, when his father died and he succeeded to the peerage. His political career, though not one which made any permanent impression on history, attracted a good deal of Maltese attention, partly from his being foreign secretary in 1852 and again in 1858–1859 (he was also lord privy seal in 1866–1868 and in 1874–1876), and partly from his influential position as an active Tory of the old school in the House of Lords at a time when Lord Derby and Mr Disraeli were, in their different ways, moulding the Conservatism of the period. Moreover his long life—he survived till the 17th of May 1889—and the publication of his Memoirs of an Ex-Minister in 1884, contributed to the reputation he enjoyed. These Memoirs, charmingly written, full of anecdote, and containing much interesting material for the history of the time, remain his chief title to remembrance. Lord Malmsbury also edited his grandfather’s Diaries and Correspondence (1844), and in 1870 published The First Lord Malmsbury and His Friends: Letters from 1745 to 1820. He was succeeded as 4th earl by his nephew, Edward James (1812–1899), whose son, James Edward (b. 1872) became the 5th earl in 1899.

MALMESBURY, a market town and municipal borough in the Chippenham parliamentary division of Wilts, England, 94½ m. W. of London by the Great Western railway. Pop. (1901),...
Malmö—Malolos

MALMÖ—

2854. It lies on a ridge surrounded on all sides except the north-west by the river Avon and a small tributary. The church of St Mary and St Aldhelm, standing high, is a majestic fragment consisting of the greater part of the nave (omitting aisles) of a Benedictine abbey church. The ruined skeleton of the great tower arches now terminates the building eastward. The nave is transitional Norman, with a Decorated superstructure including the clerestory. The south porch is one of the finest Norman examples extant, both the outer and the inner doorways (especially the first) exhibiting the typical ornament of the period in remarkable exuberance. With the exception of a crypt, the monastic buildings have disappeared. In the market square stands a fine market cross of the 16th century, borne upon an octagonal battlemented basement. Early English fragments of a hospital of St John of Jerusalem appear in the corporation almshouse. Malmesbury has an agricultural trade, with breweries, tanneries and manufactures of silk and pillow lace. It is governed by a mayor, 4 aldermen and 12 councillors.

Area, 178 acres.

Mailduphus, a Scottish or Irish monk, who came into England about 653, built a hermitage near the site of the modern Malmesbury (Maidulphi-urbis, Maldelmesburg, Malmesbi) and gathered disciples round him, thus forming the nucleus of the later abbey of which Aldhelm his pupil became the first abbot. Æthelstan, who was buried here (though his tomb in the church only dates from the 16th century), rebuilt and endowed the monastery. Round the abbey the town of Malmesbury grew up, and by the time of the Domesday Survey it had become one of the only two Wiltshire boroughs. The first charter, said to be a forgery, purports to have been given by Æthelstan. It granted to the burgesses all privileges and free customs such as they held in the time of Edward the Elder, with many additional exceptions, in return for help rendered against the Danes. The castle built at Malmesbury during the reign of Henry I. gave a further impetus to the growth of the town. Being an 11th and 13th centuries. It was not incorporated, however, until 1645, when it was made a free borough under the title of “aldermen and burgesses of the borough of Malmesbury, County Wilts.” By this charter it was governed until 1885. The borough returned two members to parliament from 1295 to 1832 when the number was reduced to one. Finally in 1885 its representation was merged in that of the county. A grant of a yearly fair on the 31st of March, the feast of St Aldhelm, was obtained from William II., and another for three days from the 25th of July from John. In 1792 fairs were held on the 28th of March, the 28th of April and the 29th of June, but in 1837 they had ceased entirely. John also granted a weekly market on Thursday. In the 16th and 17th centuries it was held on Saturday, and in 1891 on the third Wednesday in each month. In the middle ages Malmesbury possessed a considerable cloth manufacture, and at the Dissolution the abbey was bought by a rich clothier and fitted with looms for weaving. The trade in wool still flourished in 1751.

See Victoria County History: Wiltshire; and Registrum malmesburiense (1878-1880).

MALMÖ, a seaport of Sweden, chief town of the district (län) of Malmöhus, on a small bay of the Sound, 384 m. S.S.W. of Stockholm by rail. Pop. (1860), 38,054; (1900), 56,857. It is connected with Copenhagen, 174 m. W. by N., by steam-ferries, the Sound being kept open in winter by an ice-breaker. It is also the first important station in Sweden on the Berlin-Stockholm route, which crosses the sea between Sassnitz in Rügen and Trelleborg, 29 m. S.E. of Malmö. The town, which stands upon a level plain formerly had strong fortifications, of which only the citadel (Malmöhus) remains; in it the earl of Bothwell was imprisoned by Frederick II. of Denmark for some time after his departure from Scotland in 1367. The town-hall (1346, largely restored in 1864) contains a handsome chamber, the Knutstal, formerly used by the council of the guild of Canute. The hall fronts the central square (Stortorg) which is planted with trees and contains a colossal statue of Charles X. by Johan Helius Börjeson (b. 1835) erected in 1896. The most notable church is that of St Peter (Peterkyrka), dating in part from 1319. Malmö is second to Stockholm as an industrial centre. There are breweries and large works for the manufacture of machinery, among which may be mentioned the Kockum mechanical works, with yards for the construction of vessels of war, and others; of cotton and woollen goods, gloves, chocolate, sweetmeats and tobacco. A large export trade is carried on in butter and other agricultural produce, and matches. Coal is the chief import. The harbour includes an outer harbour of 22 ft. depth, and two inner basins admitting vessels of 21 ft. draught, with dry dock and patent slip. Malmö returns four members to the second chamber of the Riksdag (parliament).

Malmö (Malmhauge, Malmey, Malmöe, Malmough), sometimes called Ancona Scantorum or Ellenbogen, first appears in history about the middle of the 13th century. During the Hanseatic period it was the most important commercial town on the Sound, but in the 16th and 17th centuries greatly lost ground owing to the decay of its herring fisheries and the rise of its rival, Copenhagen. Its modern prosperity is largely due to the enterprise of Frans Snell, one of its merchants in the second half of the 18th century, who first constructed the harbour.

MALMSEY, a strong sweet wine, originally made at Monemvasia (Gr. Μονεμβασια), Napoli di Malvasia, in the Morea, Greece. The name of the place was corrupted in Med. Lat. into malvasia, whence the English form of the word. The corruption malvasia gives the O. Fr. malvoisie, from which comes the alternative English form "malvoisie." The wine is now made not only in Greece but also in Spain, Madeira and the Azores.

MALOCELLO, LANCILOTO ("Lanzarote, the 'Lancelot Maloisiel' of the French"), leader of the first of modern European oceanic enterprises. This was a Genoese expedition, which about 1417 seems to have sailed into the Atlantic, re-discovered "the Portuguese Islands" on its return, and made settlement of a conquest and settlement in one of the most northerly islands of this archipelago, still known (after the Italian captain) as Lanzarote. According to a Spanish authority of about 1345, the anonymous Franciscan's Conocimiento de todos los reinos, "Lanzarote" was killed by the Canarian natives; but the castle built by him was standing in 1402-1404, when it was utilized for the storage of grain by the French conquerors under Gadifer de la Salle. To Maloello's enterprise, moreover, it is probable that Petrarch (born 1304) alludes when he tells how, within the memory of his parents, an armed fleet of Genoese penetrated to the "Fortunate"; this passage some would refer, without sufficient authority, to the expedition of 1291. Maloello's name and nationality are certainly preserved by those early Portolani or scientific charts (such as the "Dulcert" of 1339 and the "Laurentian Portolan" of 1351), in which the African islands appear, for the first time in history, in clear and recognizable form. Thus Dulcert reads Insulae de Lanzarotus et Madei, the Laurentian map I. de Lanzaro, against Lanzarote Island, which is well depicted on both designs, and marked with the cross of Genoa. The Conocimiento (as noticed above) explicitly derives the island-name from the Genoese commander who perished here. Maloello's enterprise not only marks the beginning of the overseas expansion of western Europe in exploration, conquest and colonization (after the age of Scandinavian world-roving had passed); it is also probably not unconnected with the great Genoese venture of 1291 (in search of a waterway to India, which soon follows), with which this attempt at Canarian discovery and dominion has been by some unjustifiably identified.

MALOLOS, a town and the capital of the province of Bulacan, island of Luzon, Philippine Islands, on a branch of the Pampanga
Grande river. Pop. (1902), after the annexation of Barasoain and Santa Isabel, 27,025. There are thirty-eight villages, or barrios, of which eight had, in 1903, 1000 inhabitants or more. The principal language is Tagalog, but Spanish is spoken to some extent. Malolos is served by the Manila & Dagupan railway, and is a trade centre of considerable importance. The cultivation of rice is an important industry. In 1898-99, during the Filipino revolt, Malolos was the seat of the rebel government, but it was captured and reduced to desolation in March 1899. In 1904 a new municipal school building, a municipal market and a provincial building were erected.

MALONE, EDMOND (1741-1812), Irish Shakespearian scholar and editor, was born in Dublin, on the 4th of October 1741, the son of a barrister and a member of the Irish House of Commons. He was educated at Trinity College, Dublin, and was called to the Bar in 1767. The death of his father in 1774 led him to abandon the law, and he went to London, where he frequented literary and artistic circles. He frequently visited Dr Johnson and was of great assistance to Boswell in revising and proof-reading his Life, four of the later editions of which he annotated. He was intimate with Sir Joshua Reynolds, to whom he sat for a portrait now in the National Portrait Gallery. He was one of Reynolds' executors, and published a posthumous collection of his works (1798) with a memoir. Horace Walpole, Burke, Canning, Lord Charlemont, and, at first, George Steevens, were among Malone's friends. Encouraged by the two last he devoted himself to the study of Shakespearian chronology, and the results of his "Attempt to ascertain the Order in which the Plays of Shakespeare were written" (1798) are still largely accepted. This work was followed in 1780 by two supplementary volumes to Steevens's version of Dr Johnson's Shakespeare, partly consisting of observations on the history of the Elizabethan stage, and of the text of doubtful plays; and this again, in 1783, by an appendix volume. His refusal to alter some of his notes to Isaac Reed's edition of 1785, which disagreed with Steevens's, resulted in a quarrel with the latter. The next seven years were devoted to Malone's own edition of Shakespeare in eleven volumes, of which his essays on the history of the stage, the biography of Shakespeare, and his attack on the genuineness of the three parts of Henry VI., were especially valuable. His editorial work was lauded by Burke, criticized by Walpole and damned by Joseph Ritson. It certainly showed indefatigable research and proper respect for the text of the earlier editions. Malone published a denial of the claim to antiquity of the Rowley poems (see CHARTERERS), and in this (1782) as in his edition of the Independence of the Ireland MSS. (see IRELAND, WILLIAM HENRY) as forgeries, he was among the first to guess and state the truth. His elaborate edition of Dryden's works (1800), with a memoir, was another monument to his industry, accuracy and scholarly care. In 1801 the university of Dublin made him an LL.D. At the time of his death, on the 25th of April 1812, Malone was at work on a new octavo edition of Shakespeare, and he left his material to James Boswell the younger; the result was the edition of 1821—generally known as the Third Variorum edition—in twenty-one volumes. Lord Sunderlin (1738-1816), his elder brother and executor, presented the larger part of Malone's splendid collection of books, including dramatic varieties, to the Bodleian Library, which afterwards bought many of his MS. notes and his literary correspondence. The British Museum also owns some of his letters and his annotated copy of Johnson's Dictionary.

A memoir of Malone by James Boswell is included in the Prolegomena to the edition of 1821. See also SIR J. PRIOR'S Life of Edmond Malone (1860).

MALONE, a village and the county-seat of Franklin county, in the township of Malone, in the N.E. part of New York, U.S.A., about 60 m. E.N.E. of Ogdensburg. Pop. (1890), 4986; (1900), 5935; (1910, state census), 6478; (1920), 6497. It is served by the New York Central & Hudson River and the Rutland (N.Y. Central Lines) railways. The village has a Memorial Park, Arsenal Green, on the site of an arsenal and parade-ground sold by the state in 1850, a state armoury, the Northern New York Institute for Deaf Mutes, Franklin Academy, St. Joseph's Ursuline Academy, and a detention-house for Chinamen entering the state from Canada. From Malone tourists visit the Great North Woods, in the Adirondack foothills, about 15 m. distant. Iron ore and Potsdam sandstone are found near Malone. In the surrounding region, hops, potatoes, &c., are grown, and there are dairying and livestock interests. The village is a centre for the collection of hides and pelts. It manufactures woollen goods, paper and pulp, &c., and has foundry and machine shops and car repair shops. Malone, being on the line of communication between lakes Champlain and Ontario, was of strategic importance in the war of 1812, and later was twice the rendezvous of Fenians for attacks on Canada. The township of Malone was settled and erected from Chateaugay in 1855. The village was first known as Hatson, was named Ezraville, in honour of Ezra L'Hommedieu in 1808, received its present name in 1812, and was incorporated in 1853.

MALONIC ACID, C₃H₅O₂, or CH₃(COOH), occurs in the form of its calcium salt in the sugar beet. It was first prepared in 1858 by V. Dessaignes, who obtained it by oxidising malic acid (Ann., 1858, 107, p. 251). It may also be obtained by oxidising allylene and propylene with cold potassium permanganate solution, by the hydrolysis of barbituric acid (malonyl urea) with alkalis (A. Baeyer, Ann., 1864, 130, p. 143); by the hydrolysis of cyanacetic acid (H. Kolbe, Ann., 1864, 131, p. 349; H. Muller, Ann., 1864, 131, p. 352), and by the action of silver oxide on β-di-chloracetic ester at 125° C. (O. Wallach, Ann., 1878, 193, p. 25).

\[ \text{C}_2\text{H}_4\text{CHOOH}_2 + \text{Ag}_2\text{O} + \text{H}_2\text{O} = 2\text{AgCl} + \text{HOOC-CH}_2\text{COOH}_2 \]

It crystallizes in monocrystalline tablets, and is readily soluble in water, alcohol and ether. The acid melts at 135° C., and at a higher temperature it rapidly decomposes into acetic acid and carbon dioxide. When heated with bromine and water to 100° C. it forms tribromacetic acid, some bromoform being produced at the same time. Malonic acid, as well as its esters, is characterized by a large number of condensation products it can form. In the presence of a dehydrating agent (such as acetic anhydride), it combines with aldehydes to form compounds of the type R·CH·C(=COOH)₂, or their decomposition products (formed by loss of CO₂) R·CH·COOH.

Many salts of the acid are known, and with the exception of those of the alkali metals, they are difficulty soluble in water. Many esters of malonic acid have been prepared, the most important being the diethyl ester (malonic ester), CH₃COOEt₂, which can be obtained by dissolving monochloraetic acid in water, neutralizing the solution with potassium carbonate, and then adding potassium hydroxide. The diethyl ester undergoes hydrolysis on warming the mixture until the reaction begins. When the reaction has finished, the whole is evaporated and heated to about 130°-140° C. and then allowed to cool. The mass is then covered with two-thirds of its weight of alcohol, and saturated with hydrochloric acid gas. The whole is then poured into ice-cold water, extracted by ether and the ethereal solution distilled (L. Chisen, Ann., 1883, 218, p. 131). It is a colourless liquid boiling at 197°-795°-2 C. (W. H. Perkin). It is a most important synthetic reagent; with sodium or sodium ethane it forms sodio-malonic ester, which reacts readily with allyl halides, forming allyl malonic esters, which are again capable of forming sodium derivatives, that by further treatment with allyl halides yield the di-allyl malonic esters. On heating the mono-and di-allyl malonic acids which, on heating, are readily decomposed, with evolution of carbon dioxide and the formation of monoo- and di-allyl acetic acids. The scheme of reactions is shown thus:

\[ \text{CH}_3\text{(COOR)₂} + \text{CH}_3\text{Na} \rightarrow \text{CH}_3\text{CH}_2\text{COOR} + \text{NaOH} \]

\[ \text{CO}_2 + \text{CH}_3\text{R} \rightarrow \text{CO} + \text{CH}_3\text{R} \]
The half nitride of malonic acid is cyanacetic acid, CN-CH₂-COÖH, which, in the form of its ester, may be obtained by the action of a solution of potassium cyanide on monochloracetic acid. The solution obtained is neutralized, concentrated on the water-bath, digested with powdered charcoal, and then allowed to cool. It is then distilled into the lead salt, which is decomposed by sulphuric acid and the solution is carefully concentrated (Th. Meves, Ann., 1867, 143, p. 201). It melts at 70°C and at higher temperatures decomposes, with the evolution of carbon dioxide and formation of aceto-nitrite, CH₂-CN. The true nitride of malonic acid is methylene cyanide, CH₂(CN)₂, which is obtained by distilling a mixture of cyanacetamide and phosphorous pentoxide. It is a crystalline solid, which melts at 205-208°C and boils at 218-219°C, and is readily soluble in alcohol and ether.

MALORY, SIR THOMAS, translator and compiler of the famous English classic, the Morte d'Arthur. Previous to the publication of Professor Kittredge's monograph, Who was Sir Thomas Malory? the identity of this writer remained an unsolved problem. Mr. Sidney Lee, in the Dictionary of National Biography, was compelled to admit that he could find no one of that name fulfilling the necessary conditions. Of direct evidence we have very little; in the concluding passage of the book the author asks the prayers of the reader for "Sir Thomas Malore knyght," and states that the book was ended "the ix. yere of the regnye of Kyng Edward the fourth." Caxton, in his preface, says that he printed the book "after a copuye unto me delivered whyche copye Sir Thomas Malorye dyd take out of certeyn bookes of frenshe and reduced it in to Englyshe"; in his colophon he repeats this statement, adding that he himself is responsible for the division of the work into books and chapters, and that it was printed in 1485. It will be noted that Caxton does not say that he received the book from Malory, only that he had received a copy made by Malory; from this Professor Kittredge draws the conclusion that the compiler was no longer living. The problem then is to find a Thomas Malory who was (a) a knight, (b) alive in the ninth year of King Edward IV. (March 25, 1465-March 14, 1470), and (c) who was no longer living in July (or June) 1485.

All these conditions Professor Kittredge finds fulfilled in the life of Sir Thomas Malory, knight, of Newbold Reval (or Newbold Nubold), M.P. for Warwickshire in 1445. The date of Sir Thomas's birth is uncertain, but he succeeded his father, Sir John, in 1433 or 1434. Previously to this he had served in France, in the retinue of the earl of Warwick, most probably during the time that that nobleman held the office of captain of Calais. It seems probable that he is also to be identified with a "Thomas Malorie, miles," who in 1465 was, on account of the part played by him in the Wars of the Roses, excluded with several others from the operation of a pardon issued by Edward IV. As, however, on the death of Sir Thomas on the 14th of March 1470, there was no difficulty as to inheritance, his estates passing to his grandson, he must, if this identification be correct, have come under the general amnesty of 1466. It will be seen, therefore, that so far as it is in our power to state the question this Sir Thomas Malory fulfils all the necessary conditions.

It is interesting to note that the career of the earl of Warwick in France was marked by certain picturesque and chivalric features which might well impress the imagination of a young retainer. John Rous, in his Life of Richard Earl of Warwick, tells us that at a certain tourney held near Calais at Christmas-tide, Earl Richard appeared three days running in different armour, overthrowing his adversary on each occasion—an exploit obviously imitated from the chivalric romances of the period.

The work with which Malory's name is connected is an abridged compilation of the great body of Arthurian romance in its latest form. The Merlin (Vulgate and Suite), Tristan, Lancelot, Queste and Mort Artus are all represented, the only branch omitted is that dealing with the early history of the Grail. The book is dedicated to the labours of Dr Oskar Sommer, from whom we can now assign the majority of the books to their separate sources, although certain stories, such as the adventures of Sir Garet under the pseudonym of Beaumains, the handling of Sir Urre of Hungary, and the details of the abduction of Guenevere by Meleagaunt, still remain unidentified. But we do not yet know whether Malory himself was responsible for this selection, or whether he found it ready to hand in a MS., the "Frenshie Booke" to which he often refers. To make such a compilation at first hand, considering the extent of the ground covered, would involve an enormous amount of study and selection, and the access to a very large library—conditions which scarcely seem to fit in with the social position and activities of Sir Thomas. On the other hand it is undeniable that the medieval copyists, at the instance of their patrons, did make compilations from the various romances within their reach, such as e.g. the enormous codex 112 (fonds Franc.) of the Bibliothèque Nationale, which includes large sections of the Tristan, the Lancelot, and the Merlin Suite. Taking into consideration alike what Malory retains and what he omits, it seems most probable that he was in possession, not of complete copies of the romances, but of one or more volumes of compilations from these sources.

From the point of view of matter it must be admitted that the Morte d'Arthur does not represent the Arthurian cycle at its best, but rather in the period of its decadence; nor does Malory in any way endeavour to overcome the difficulties caused by the juxtaposition of a number of independent (and often contradictory) versions. This is especially noticeable in his treatment of Gawain; in the section derived from the Lancelot and Mort Artus he is a good and valiant knight, "a ful noble knyghte as ever was borne," in those derived from the Tristan and the Queste, he is treacherous, dissolute, and a murderer of good knights.

The great charm of Malory's work lies in its style; stately, earnest and dignified, it has lent to the relations between Lancelot and Guenevere a character of truth and vitality in which the French original is wholly lacking. Malory achieved a remarkable feat—he took the Arthurian story in its worst and weakest form and he imparted to it a moral force and elevation which the cycle, even in its earlier and finer stage, had, save in the unique case of Von Eschenbach's Parzival, never possessed. While genuine lovers of the Arthurian cycle must regret that the romances should only be known to the great majority of English readers through the versions of Malory and Tennyson, it is impossible to withhold from the Morte d'Arthur the admiration due to an imperishable monument of English language and literature.

See Who was Sir Thomas Malory? G. L. Kittredge (Harvard Studies and Notes, vol. v., 1896); Morte d'Arthur, ed. by Dr Oskar Sommer (an exact reproduction of the original text in 2 vols.); Notes, iii. a study on The Sources of Malory. The sections on Lancelot and Queste are informally very defective, and these cl. The Legend of Sir Lancelot, Grimm Library, vol. xii. (J. L. W.)

MALOT, HECTOR HENRI (1830-1907), French novelist and man of letters, the son of a notary, was born at La Bouille (Seine Inférieure) on the 20th of May 1830. He studied law at Rouen and Paris, but literature early absorbed his attention. He collaborated in the Biographie générale de Didot, became literary critic of L'Opinion Nationale, and dramatic critic of the Lloyd français. He is the author of a long series of popular novels dealing with contemporary life, including: a trilogy of domestic novels entitled Victimes d'amour (1859, 1865, 1866); Un Beau frère (1860); Madame Oberlin (1870); Le Docteur Claude (1870); Justice (1886). Les Aventures de Romain Kalbris (1860) and Sans famille (1888) are excellent stories for children. A complete edition of Hector Malot's works appeared in 1894-1897. He died at Vincennes in July 1907.

MALOU, JULES ÉDOUARD XAVIER (1810-1886), Belgian statesman, one of the leaders of the clerical party, was born at Ypres on the 19th of October 1810. He was a civil servant in the department of justice when he was elected to the Chamber of Deputies by his native constituency in 1844, and, after some time governor of the province of Antwerp. He was minister of finance in the coalition ministry of J. B. Nothomb in 1844, and formed with B. T. de Theux a Catholic cabinet in 1846, which was overthrown in the Liberal victory of 1847. Malou
then became a member of the senate, and his party only regained ascendency in 1870. The extreme clerical ministry of Baron d'Anethan, a minister in 1872, after serious rioting in Brussels, and Malou was the real, though not the nominal, head of the more moderate clerical administrations of de Theux and Aspremont-Lynden (1876-1878). He was wise enough to disavow the noisy sympathy of Belgian Ultramontane politicians with the German victims of the Kulturkampf, and, retaining in his own hands the portfolio of finance, he subordinated his clerical policy to a useful administration in commercial matters, including a development of the railway system. It was only after the fall of the ministry in 1878 that he adopted a frankly clerical policy, and when he became chief of a new government in June 1884 he proceeded to undo the educational compromise of his predecessors in the Frère-Orban ministry. His legislation in favour of the Catholic schools caused rioting in Brussels, and in October the king demanded the retirement of MM. Jacobs and Woeste, the members of the cabinet against whom popular indignation was chiefly directed. Malou followed them into retirement, and died at Woluwé Saint Lambert, in Brabant, on the 11th of July 1886. He was a financier of great knowledge and experience, and his works (of which a long list is given in Koninck’s Bibliographie nationale du Belgique, in three volumes, 1885-1889) are on financial questions, edited by him for the Chamber of Deputies, besides pamphlets on railroad proposals, mining and other practical questions. His brother Jean Baptiste Malou (1809-1864) was a well-known divine.

MALOUET, PIERRE VICTOR, BARON (1740-1814), French publicist and politician, was born at Riom (Puy-de-Dôme) on the 11th of February 1740, the son of a lawyer. He entered the civil service and was employed successively at the French embassy in Lisbon, in the administrative department of the duc de Broglie's army, as commissary in San Domingo from 1767-1774, and, after his return to France, as commissary-general of the marine. In 1776 he was entrusted to carry out plans of colonization in French Guiana, but was superseded in 1779. On his return to France he was well received at court, and the execution of his plans in Guiana was assured. He became intendant of the port of Toulon, and in 1789 was returned to the states-general, where he soon became well known as a defender of the monarchical principle. He emigrated to England in September, 1792, but shortly afterwards he returned to France, and was put on the list of the enemies of the republic. He was soon called to the defence of Louis XVI. His name was erased from the list of emigrants in 1801 by Napoleon, who restored him to his position in the service and sent him to Antwerp as commissioner-general and maritime prefect to superintend the erection of defence works, and the creation of a fleet. He entered the council of state in 1810, but, having offended the emperor by his plainness of speech, he was disgraced in 1812. At the Restoration, Louis XVIII. made him minister of marine; and he died on the 7th of September 1814.

The most important documents for his domestic and colonial policy are a Collection de ses opinions à l'Assemblée Nationale (3 vols., 1791-1792); and Collection de mémoires et correspondances officielles de Viollet (1813), containing some letters and memorials on the Guiana française et hollandaise (5 vols. 1802).

MALPIGHI, MARCELLO (1626-1694), Italian physiologist, was born at Crevalcure near Bologna, on the 10th of March 1628. At the age of seventeen he began the study of philosophy; it appears that he was also in the habit of amusing himself with the microscope. In 1640 he started the study of medicine; after four years at Bologna he graduated in the faculty of medicine, and once applied to be admitted to the university, but it was not till after three years (1659) that his request was granted. A few months later he was appointed to the chair of theoretical medicine at Pisa, where he enjoyed the friendship and countenance of G. A. Borelli. At the end of four years he left Pisa, on the ground of ill-health, and returned to Bologna. A call to be professor primarius at Messina (procured for him through Borelli, who had in the meantime become professor there) induced him to leave Bologna in 1662. His engagement at Messina was for a term of four years, at an annual stipend of 1000 scudi. An attempt was made to retain him at Messina beyond his term, but his letters went unheeded for his native university, and he went to the next stage of his career. In 1661, being then in his sixty-fourth year, and in failing health, he removed to Rome to become private physician to Pope Innocent XII., and he died there of apoplexy three years later, on the 30th of November 1664. Shortly before his death, he drew up a long account of his academical and scientific labours, correspondence and controversies, and committed it to the charge of the Royal Society of London, a body with which he had been in intimate relations for more than twenty years. The autobiography, along with some other posthumous writings, was published in London in 1666, at the cost of the Society. The personal details left by Malpighi are few and dry. His narrative is mainly occupied with a summary of his scientific contributions and an account of his relations to contemporary anatomists, and is entirely without graces of style or elements of ordinary human interest.

Malpighi was one of the first to apply the microscope to the study of animal and vegetable structure; and his discoveries were so important that he may be considered to be the founder of microscopic anatomy. It was the practice to open animals alive, and some of the greatest discoveries in the microscopical study of the frog’s blood, although they are the parts of the blood by which its movement in the capillaries is made visible. His discovery of the capillary circulation was given to the world in the form of two tractatus (1661 and 1662) entitled De circulatione sanguinis et de corporibus microscopiciis in animalibus, and in 1664 and 1669 and reprinted at Leiden and other places in the years following; these letters contained also the first account of the vesicular structure of the human lung, and they made a theory of respiration for the first time possible. The achievement that comes next both in importance and in order of time was a demonstration of the plan of structure of secreting glands; against the current opinion (revived by F. Ruyse four years later) that the glandular structure was essentially that of a closed vascular coil from which the secretion exuded, he maintained that the secretion was formed in terminal acini standing in open communication with the ducts. The name of Malpighi is still associated with his discovery of the soft or mucous glandular structure, which is present in the pancreas, in the bile duct, in the lining of the stomach, and throughout the alimentary canal; the glands are described as mucous, and are distinguished by acini; he gave the first account of the glandular structure, and that other it was of glandular structure and that it secreted the "vital spirits." At an early period he applied himself to vegetable histology as an introduction to the study of the structure of the body and of the animal tissues, and he was acquainted with the spiral vessels of plants in 1662. It was not till 1671 that he wrote his Anatome plantarum and sent it to the Royal Society, who published it in the following year. An English work under a similar title (Anatomy of Vegetables) had been published in London a few months earlier, by Nehemiah Grew; so that Malpighi’s priority as a vegetable histologist is not so incontestable as it is in animal histology. The Anatome plantarum contains an account of the structure of the plant cell, and the account of the embryo is accompanied with good plates of the development of the chick (especially of the later stages) in many points more complete than that of Harvey, although the observations were needlessly lessened in value by being subjected to the most physical notion of "praeludization" in the undeveloped ovum.

He also wrote Epistola anatomicae Marc. Malpighii et Car. Fracassati (Amsterdam, 1663) (on the tongue, brain, skin, omentum, and lymphatic glands); and De circulatione sanguinis in corpusculo in corpore humano (Amsterdam, 1663; London, 1669, Opera postuma, et vita seipso scripta (London, 1697; another edition, with preface and additions, was published at Amsterdam in 1700.) An edition containing all his works except the last two was published in London in 1687, in 2 vols. folio, with portrait and plates.

MALPLAQUET, a village of France in the department of the Nord, close to the Belgian frontier and about 10 miles S. by E. of Mons, famous as the scene of the battle, September 1709, between the Allies under the duke of Marlborough and Prince
MALPLAQUET

Eugène and the French commanded by Marshal Villars, in which the former were victorious. The country to the west and south of Mons is enclosed by a semicircular wall of woods and broken ground, through which there are only two important gaps—that of Jemappes (famous in 1792) to the west, and that of Aulnois, in which stands the village of Malplaquet, to the south. In the latter gap and the woods on either side Villars took up his position facing north-eastwards, on August 29/September 9. The forces in presence, over 90,000 on each side, were exceptionally large, and the French army in particular represented the spirit of its nation to a degree unusual in the armies of that time. Villars was the best general in the service of Louis XIV. and the veteran Marshal Boufflers, though senior to him, had volunteered to serve as his second in command. Marlborough and Eugène lay with their army between Mons and the French camps, which were almost within cannon shot. Marlborough's own wish was for an immediate battle, but he was opposed by the Dutch deputies at his headquarters, and even by Eugène, so that it was only on August 31/September 1 that the attack actually took place. Villars had made full use of his respite. The French right stood at the fringe of the forest of Lanière, the left was strongly posted in the midst of the wood of Taisnière, and across the two and a half miles of open ground between the woods the position was entrenched with several successive lines of works. The troops were almost equally distributed along the whole line as usual, and the cavalry was massed in rear of the infantry. In the Allied army the mounted troops were also kept back, but for the most part distributed to the various infantry commands.

The intention of Marlborough and Eugène, when on the morning of the battle they examined this formidable position, was to deliver the main attack upon the French left wing, combining the assaults of several columns on its front and flanks. In this quarter the French not only held the interior of the wood but also were thrown forward so as to occupy the edges of its north-eastern salient, and upon the two faces of this salient Count Lottum (1650-1719) with the Prussians, and Count von der Schellenburg (1661-1747) with the Austrian infantry were to deliver a double attack, while farther to the Allied right a column under the English General Withers was detached to make a wide turning movement through the woods. Marlborough took command on the right, Eugène on the left. The centre, which was intended only to observe the enemy until the decision had been forced at the wood of Taisnière, consisted of Lord Orkney's British corps and the prince of Orange's Dutch contingent. These extended across the Trouée d'Aulnois as soon as the combined attack of Lottum and Schellenburg opened. The general advance was covered by a heavy cannonade, and the salient of the Taisnière wood was duly attacked on its two faces by the Prussians and Austrians about 9 a.m. They encountered a sterner resistance than in any of the battles and combats of the past seven campaigns, for on this field the defenders were fighting, not as hitherto for the interests of their king, but to defend their country, and the regiments of Picardie and Champagne which held the salient were the oldest and most famous of the French line. Lottum attacked the works on the eastern edge, again and again without success, until three British battalions had to be sent to reinforce him, and Marlborough placed himself with a corps of cavalry in close support. At last the enrenchments were stormed. Schellenburg, with the Austrians, had by this time fought his way through the woods and under-growth, and the united force pressed back the French farther and farther into the wood. Still, so stubborn was the defence and so dense the wood that the impetus of the assault died away and the troops on both sides broke up into small disconnected bodies, fighting too fiercely to be amenable to superior control.

But the French were not reinforced from their right wing as Villars expected. The prince of Orange, far from merely observing the hostile right as he had been ordered to do, committed his corps, very early in the battle, to a serious assault upon it, which Boufflers repulsed with enormous loss. The Dutch infantry never recovered from its casualties on this day, and the memory of Malplaquet was strong even at Fontenoy nearly forty years afterwards. Some Hanoverian troops which took part in this futile attack suffered equally heavily. The only advantage to the Allies—an advantage which, as it happened, counted for much—was that Boufflers did not dare to send reinforcements to the hard-pressed left wing. Thanks to this the Austrians and Prussians, with the English detached to their aid, made steady progress in the wood of Taisnière. Villars launched the "Irish brigade" to check the advance of the Allies, and this famous corps charged into the forest. Villars, Eugène and Marlborough personally led their troops in the encounter which followed. Eugène was wounded, but refused to quit the field. Villars was more seriously hurt, and after trying in vain to direct the fighting from a chair was carried insensible from the field. At this crisis General Withers, who commanded the force that had been ordered to turn the French extreme left, and had fought his way through the forest, appeared on the scene. The British 18th regiment (Royal Irish), encountering the French Royal Irlandais, put it to the rout, and Villars's counterstroke was at an end. The French maintained themselves on this side only by the aid of troops drawn from the centre and right, and this gave the Allied centre the opportunity which the prince of Orange had so rashly anticipated. The great weight over the open was carried out, in spite of the previous repulse, with the greatest determination. Preceded by forty guns, the corps of the prince of Orange and Lord Orkney swiftly carried the first line of works. The Allied cavalry then pushed out to the front, and horse, foot and artillery were combined in the last advance. Boufflers's cavalry masses, coming into play for the first time, fought hard, and the struggle fluctuated with the arrival of successive reserves on either side, but in the end, shortly before 3 p.m., Boufflers (who had been in command since Villars's fall) decided to retreat. The Allies had no troops left intact for the pursuit, and those engaged had expended their last efforts. Moreover Boufflers, experienced soldier as he was, drew off his men before they had lost their order and discipline.

![Sketch plan of MALPLAQUET](http://www.somerset.in)
Thus this "very murdering battle" as Marlborough called it—the last and greatest pitched battle of the war—was almost barren of results. The Allies lost not less than twenty thousand men, or nearly a quarter of the whole force, the thirty battalions of the Dutch infantry losing half their numbers. On the French side there were some twelve thousand casualties. If further evidence were necessary to prove that the French fought their hardest, it could be found in the fact that whereas in almost every other battle, from 1660 to 1792, there were deserters and prisoners by the thousand, at Malplaquet only 500 of the French fell into the hands of the victors unwounded.

MALSTATT-BURBACH, a town of Germany, in the Prussian Rhine province on the right bank of the Saar (Sarré), which separates it from Saarbrücken. Pop. (1900), 31,195. It lies in the midst of an important coal-mining and industrial district, and is itself little more than a long and narrow row of manufactories and workmen's houses. The largest factories are engaged in the production of iron, steel and cement. There is a large wharf on the river for the export of coal.

Malstatt received municipal rights in 1321. These, however, were afterwards resigned to the newer town of Saarbrücken, and in 1818 Malstatt and Burbach were two small villages with a joint population of only about 800. About the middle of the century the population began to increase rapidly, in consequence of the development of the mining industry of the district and the extension of the railway system, and in 1874 the two villages were united to form a town.

MALT (O. Eng., meal; O. Sax., malt; O. Teut., mollis; Mod. Ger., Mälz; Scand., malt; probably derived from the Sanskrit mṛdu, soft, thus 'having reference to the fact that malt is raw grain rendered soft or tender'), the name given to grain in which germination has been caused to proceed to a certain stage and has then been arrested by the removal of water and the application of heat. During this limited germination enzymes are developed (see Fermentation), and the constituents of the grain modified so that the finished malt, when ground and submitted to the mashing process (see Brewing), differs from the original raw grain in that the greater portion dissolves. This solubility is, however, a direct one to a slight extent only; it is due for the most part to the action of the malt enzymes, diastase, &c. on the constituents of the grain, the main portion of which are of themselves insoluble. Thus starch, the main constituent of all gramimaceous seeds, probably exists in the same condition in raw grain and in malt. When however the malt is mashed, the starch is attacked by the enzyme diastase, and is broken down by the process of hydrolysis into a mixture of soluble compounds, e.g. the crystalline sugar, maltose, and a number of gummy substances known as maltodextrins. But to a certain extent starch and other carbohydrate substances are rendered directly soluble and diffusible during the malting process, some of the products serving the respiratory needs of the growing germ, others being assimilated by the plantlet and reconverted into reserve carbohydrates in the tissues of the germ and rootlets, whilst the remaining portions are retained as such in the finished malt. Similarly certain of the nitrogenous constituents of the grain, the proteins, are broken down and rendered soluble by proteolytic enzymes, the products being assimilated to a certain extent by the germ and rootlets, by the cells of which they are again built up into complex proteins, whilst others remain in their simplified form. It is now known that proteolytic enzymes exist in finished malt, and that, when the mashing process is conducted under certain conditions, these are able to degrade and render soluble some of the higher proteins present in the malt. When germination is allowed to proceed as it does when the grain is planted in the soil, the whole of the contents are rendered soluble by degrees and in turn assimilated by the growing plantlet. By the limited germination which constitutes the malting process, however, the balance of soluble compounds left in the finished malt is from 15 to 25% of the total weight of the corn.

Although other seeds of the natural order Gramineae are occasionally malted, the greater portion of malt is made from the various species of Hordeum, known by the name of barley (q.v.), bigg, or bere. Indeed ordinary beer derives its characteristic flavour to the greatest extent from barley malt. A small proportion of malted oats or malted wheat is sometimes used in conjunction with barley malt for certain kinds of beer, whilst rye, maize, and even rice are occasionally malted. Barley is, however, the grain best adapted for making malt intended for brewing beer, and accordingly some space will be devoted to a description of those varieties of this grain which are used by the brewer.

Barley belongs to the genus Hordeum, of which there are numerous species and varieties. Linnaeus and the earlier botanists recognized six species of cultivated barleys, but modern botanists usually consider all cultivated barleys as belonging to one species to which the name H. sativum has been given. Körnirgke regards H. spontaneum, a very long thin-grained two-rowed barley (see below) which grows in the East, as being the parent form; but E. S. Beaven inclines to the view that wild species of more than one form were originally used as food and subsequently cultivated. The last-named author has drawn up a scheme of classification for the varieties and races of cultivated barleys.

In an ear of barley the primary axis or rachis is divided into internodes of which there may be any number up to forty. Each internode bears three single-flowered spikelets arranged alternately on either side of the rachis. In the six-rowed varieties the whole of these spikelets attain maturity, whilst in the two-rowed varieties only one on each side of the rachis, viz. the median, develops. British beer is brewed principally from the malt made from home-grown two-rowed barleys. Of late years, however, it has been found advantageous to employ a proportion of malt made from the thinner and more husky foreign barleys, mostly six-rowed varieties. The corns of two-rowed barleys are as a rule plumper than those of six-rowed barleys.

The most favourite barley for malting purposes grown in the United Kingdom is the narrow-eared two-rowed H. distichum, commonly known as Chevallier, from the name of the original cultivator, the Rev. John Chevallier. Of late years the quantity of
barley of the so-called Goldthorpe type (*H. secostron*), used for malt-
ing, has increased. The palae or outer coverings of the corns of this variety are somewhat "greasy" in appearance, and do not adhere so closely to the husk as in the Chevallier. The corns of Goldthorpe barley possess a small dimple or rasburr near the basal end. Further the basal bristle or rachilla (the prolongation of the axis or point from which the corn was originally developed) is invariably covered with long hairs, whilst in the case of Chevallier it is generally very short hairs. In the variety of Chevallier known as Archer, however, the rachilla has somewhat long hairs. Further the corns of Chevallier barley lie nearly vertical, that is almost parallel to the rachis, whereas in Goldthorpe they are spread out at a great angle, hence the name fan or peacock barley given to that variety commonly known as sprat. It is believed by some brewers that Goldthorpe barleys never yield malt of so high a quality as do Chevallier barleys. On the other hand, when well matured, Goldthorpe work evenly and freely on the malting floors; and from an agricultural point of view they have the advantage of standing up better against unfavourable weather conditions on account of their stouter straws. Numerous fresh varieties of barley are con-
tinually being introduced as a result of artificial cross-fertilization, but cross-fertilization rarely if ever occurs naturally.

Hungarian two-rowed barleys are excellent as regards quality, and command a high price. The so-called Californian Chevallier and Chilean Chevallier contain a certain admixture of the six-rowed *H. vulgare*.

Of the imported thin barleys may be mentioned Brewing Cal-
ifornian, Brewing Chilian, Danubian and Smyrna (Yerli), all for the most part six-rowed varieties; also Ouchak, consisting principally of the six-rowed variety. For the manufacture of grain spirit a malt of high diastatic activity is required, and this is largely made from a very thin barley shipped from Odessa.

In the common six-rowed English barley or Scottish here (*H. vulgare*), the two lateral rows of spikelets springing from one side of the rachis, either partially or entirely intersect and overlap the alter-
nate lateral spikelets which spring from the opposite side of the rachis.

This has given rise to the term "four-rowed barley." Figs. 1-4 show some typical barleys in the ear.

The production of new varieties by cross-fertilization has of late years attained a degree of almost mathematical precision by the application of the law of inheritance first discovered by Gregor Mendel in 1866, and brought to light in 1901 independently by de Vries, Correns and Tschermak.

**Constitution of Barley.**—A grain of barley is shuttle-shaped; the end containing the germ which was originally attached to the rachis is known as the proximal end, whilst the opposite end of the corn is called the distal end. A deep furrow runs down the more convex side, which is accordingly denoted the ventral side, the opposite side being distinguished as the dorsal side. Within the ventral furrow at the proximal end is the rachilla already referred to. The skin or husk of a barleycorn consists of two palaeae, one adhering to the dorsal side (the palea inferior) and the other to the ventral side (the palea superior); the former overlaps the edges of the latter. The awn or beard is merely an elongation of the palea inferior.

If the two palaeae are removed from a barleycorn after soaking it in water, it will be seen that there are other skins completely enveloping the embryo and endosperm. These are the true skins, and are known as the pericarp and the testa respectively. It may here be mentioned that A. J. Brown has shown recently that the embryo and endosperm of a barleycorn are enclosed in a semi-permeable membrane, i.e. one which allows the passage of water to the interior of the corn, but not of certain salts and acids. This property appears to be associated with one of the layers of the testa. Next to these skins will be seen the triple layer of thick-walled square-shaped aleurone cells.

The histology of the barleycorn is best studied by the examination of sections under the microscope. The grain consists of two main portions, the embryo or germ, and the endo-
sperm, the storehouse of reserve materials for the growing plant.

The accompanying illustrations show portions of longitudinal sections of a barleycorn magnified to different degrees.

On examining fig. 5, which represents a section of the germ en-
d of a grain of barley cut through the ventral furrow, it will be noticed that the rudimentary leaves, stem and roots are distinguishable. The embryo lies embedded in a mass of cells, the part dividing it from the endosperm being known as the scutellum. Special note should be taken of the elongated cells known as the absorptive epithelial layer, which has certain very important functions to fulfil during the process of germination, notably in feeding the embryo when it begins to develop into a young plant. Next to this, actually between the scutellum and the endosperm, will be seen a layer of empty cells. These at one time in the history and the development of the corn contained starch granules, but this starch was absorbed during its later development by the embryo. It will be observed further that the endosperm is filled with a network of thin-walled cells closely packed with starch granules, and smaller granules of protein matter (fig. 6). Nearest the skin will be seen the triple layer of aleurone cells already referred to (fig. 7).

**Germination.**—The barleycorn in its resting stage is in a state which may be described as one of dormant vitality; it
MALT

501

cells of the scutellum, which previously were almost free from starch; the protein matter deposited in the latter disappears to a considerable extent, and the protoplasmic content of the cells assumes a very granular appearance. The pointed mass of cells constituting the root-sheath is pushed forward by the root which protrudes through the base of the grain. It is at this stage that the barley is said by the maltster to "chit." After the first rootlet has broken through the ends of the sheath, it is followed by others. The cotyledonary sheath begins to elongate on the third or fourth day of germination and ruptures the true covering of the seed; it then grows upwards between this and the husk and forms the acrospire or "spire" of the maltster.

According to Brown and Morris, when the first rootlet is breaking through the sheath, starch begins to appear in the tissues of the grain, also in the protoplasm of those cells which are nearest the epidermal layer, and it gradually invades the deeper-seated cells. Further the cellulose walls of the endosperm, situated immediately above the secretory layer, are partially dissolved, the dissolved matter passing into the scutellum, there to be transformed into starch. Brown and Morris state that this process gradually extends to the cellulose walls of the endosperm, and until these are affected there is no evidence of any solvent action on the starch granules themselves. Thus according to these authors the first enzyme to be formed is one which dissolves cell walls, and it was consequently termed by them a "cellulase" or "cellulolytic" enzyme. They assert further that the so-called mealy or modified condition, which the maltster desires to bring about to the fullest degree, depends on the extent to which the cell walls have been affected, and they enter into a minute description of the entire disappearance of these during the malting process. On the other hand, Griess has pointed out that the action which takes place on the cell walls of the endosperm during germination does not consist in their complete solution. Schulze has shown that these cell walls consist of two carbohydrates, an araban and a xylan. Griess states that the araban is completely dissolved, whilst the xylan is more or less unaffected. The cell walls become, however, transparent so that they can only be seen in sections which have been stained; Brown and Morris examined unstained sections. The writer (A. R. Ling) has proved that the cell wall is present in the most friable and well-modified finish malt.

Condition.—Barley is bought in the open market solely on the evidence of certain external signs, and judgment can only be acquired by long experience. The corns should be plump, even in size, and the colour should be uniform from end to end. The sample should have a sweet odour, and it should be dry to the touch. The presence of light or weevilled corns may be detected by the fact that they float in water. Careless threshing or dressing is responsible for much damage done to barley. In this way many of the corns may be broken, have the paleae partly stripped off or portions removed along with the awn. All broken and dead corns are prone to become mouldy on the malting floors, the contagion thus presented becoming general. E. R. Moritz drew attention in 1893 to the ill effects of close dressing, and more recently (1905) the matter has been brought before the Highland and Agricultural Society, chiefly through Montagu Baird, who with C. H. Babington was instrumental in inducing the Board of Agriculture to publish a leaflet recommending more careful methods of threshing barley. Close dressing was at one time practised as a means of raising the bushel weight, and thus giving a fictitious value to the barley. Immature barley feels cold to the hand, has a greenish-yellow colour, and, when dry, a starved wrinkled appearance. Over-ripeness in barley is distinguished by a white dead appearance of the corn. Mature or dry grains slip through the fingers more readily than unripe or damp ones. The contents of the endosperm should present a white friable or mealy appearance when the corns are bitten or cut in two with a penknife. The condition of the grain may be determined by means of a mechanical cutter, which cuts a certain number of corns (fifty or more) at one time. Some cutters are constructed to cut the corns transversely, others to cut them longitudinally. The so-called transparence test may be used for the same purpose. It is carried out in an apparatus known as the diaphanoscope, which consists of a box fitted with a sliding tray, furnished with a certain number of shuttle-shaped holes (usually 500), each of such a size as just to hold a barley corn longitudinally. Into the portion of the box below this tray an electric lamp is placed, and the corns are looked at from above. Thoroughly mealy corns are opaque, whilst steely corns are transparent. When certain portions of a corn are steely, these present the appearance of lakes. By this means the percentage of mealy, steely, or half steely corns in a sample may readily be estimated.

E. Prior points out that steeliness of barley is of two kinds, one of which disappears after the grain has been steeped and dried, and therefore does not necessarily influence the malting value of the sample, and the other which is permanent, and therefore retards the modification of the corn. He proposes to determine what he called the coefficient of meallowness of a sample of barley by means of the formula:

\[ A = \frac{(M - M_1)}{100} \times 100 \]

in which \( A \) is the degree of meallowness, \( M \) is the percentage of mealy corns in the original barley, and \( M_1 \) is the percentage of mealy corns after steeping and drying the barley. Prior points out that, generally speaking, the degree of meallowness varies inversely as the protein content.

The physical differences between steely and mealy grains were first investigated by Johansen, who arrived at the conclusion that mealliness is always accompanied by the presence of air spaces in the endosperm. Munro and Bean confirmed and extended this. Mealy grains are found to contain a lower specific gravity than steely grains, and contain a larger amount of interstitial air. The total nitrogen content of mealy grains is less than that of steely grains. Steely grains contain a relatively high proportion of nitrogenous substances, as well as the endogenous substances, and the apparent nitrogen content is usually found to be lower, in 5% salt solution, and in alcohol of specific gravity 0.9. Mealy barley modifies better than steely during germination. The process of drying damp and under-matured barley intact at 100°F. produced an apparent nitrogen content of 12 parts in 100, whereas that of steely barley is 13 parts in 100. This is physiologically a post-ripening process, is correlated with the mealy appearance of the endosperm, H. T. Brown and his collaborators point out that thin sections of steely corns when examined under the microscope have the endosperm of the whole of the endosperm under a state of tensile stress which cannot be relaxed without breaking the grain, however, a thin section of a steely barley can be cemented to a slide with Canada balsam and then pared away with a razor, steeliness and translucency may be preserved even in the thinnest sections. The mealy appearance in the endosperm of barley is assumed to be a direct consequence of the formation of interspaces around the cell-contents and within the

---

**Fig. 7.—Section showing the aleurone layer.**

1. Starch cells; 2. Aleurone layer; 3. Layers which collectively constitute the husk.
cell walls. Under ordinary conditions it is conjectured that these interspaces are filled with air, but it is pointed out that they can also be produced under circumstances which suggest that they are at times vacuous or partly so. According to the last-mentioned authors, barley appears to originate from a system of stresses and strains which are induced within the endosperm by its gradual loss of water, a break of continuity taking place which gives rise to these interspaces when the cohesive power of the heterogeneous cell-contents falls below a certain point. It is further suggested by them that the most important factor in producing the stresses and strains is probably the shrinkage of the starch granules as their water content is reduced from 30 to about 15%. It is pointed out, however, that actual discoloration in the cell-contents can only take place when the tensile strength of the protoplasmic matrix in which the starch granules are embedded has been surpassed, and this being so it might be anticipated that those cells which contain the larger amount of protein material are probably best suited for this purpose. It has been found by F. W. Smith and others that the percentage of the cell-contents which are reduced to a semi-transparent state is closely correlated with the number of hours that the grains have been exposed to a temperature of 130° F., and that a deduction in close agreement with observed facts, steely grains being as a rule richer in protein than mealy grains.

Brown and his co-workers determine the coefficient of mealliness as a barley, as follows: Five hundred corns are cut transversely in a corn cutter and the percentage of mealy, half mealy and steely corns is noted. The number 100 is taken to represent complete mealliness, 1 complete steeliness, and 50 the intermediate class. If the percentage of each class be multiplied by its special value, and the sum of these products divided by 100, the result is the coefficient of mealliness. By steeping and drying a very steely Scottish barley, the coefficient of mealliness was raised from 29-7 to 87-1, whilst, concurrently the specific gravity fell from 1-47 to 1-286.

Barley even of the same kind varies widely in its chemical composition, but on an average the proximate constituents of British malting barleys lie within the following limits:

- Moisture: 18–12 per cent.
- Nitrogenous matters expressed as proteins: 8–15 %.
- Fat: 2–4 %.
- Starch: 60–65 %.
- Sugars: 1-5–2-0 %.
- Gums: 1-7–2-0 %.
- Fibre (cellulose): 5-2–2-5 %.
- Ash: 1-5–2-0 %.

Any sample of barley which contains more than 20% of moisture should be considered damp. The late Professor Lintner expressed the view several years ago that a good malting barley should not contain more than 10% of protein, but R. Wall asserts that in America six-rowed barleys containing a far higher percentage of protein are used successfully, indeed preferably, for malting purposes. The only precise knowledge we possess of the protein compounds of barley is due to the researches of T. B. Osborne. According to this observer, barley contains the under-mentioned compounds of this class in the following proportions:

- Soluble in water: Leucosin (albumin) 0-30 per cent.
- Soluble with cold water: Proteose 1-95 %.
- Soluble in 75% alcohol: Insoluble protein 4-50 %.
- Total: 10-75 %.

It should be pointed out here that the above are only average values for the particular samples of barley investigated. Undoubtedly the nitrogenous constituents of different barleys vary widely in nature as well as in amount.

Raw barley contains enzymes, thus diastase of translocation, so called by Horace T. Brown and G. H. Morris, and catalase (H. van Lare). Proteolytic enzymes appear only to arise with the beginning of germination; but it has been asserted that raw barley contains proenzymes (zymogens), which can be rendered active by treatment with dilute lactic acid at an appropriate temperature. The action of the diastase of raw barley on starch has been studied by Julian L. Baker.

Barley should not be cut until it is properly ripe, but over-ripeness is much more to be guarded against by the maltster than premature cutting, as it is accompanied by a loss in germinative power. Moreover, unripe corn may to a certain extent be matured in stack, whilst a great improvement in germinative capacity is frequently produced by sweating. Very wet seasons are prejudicial to the ripening of the grain, and when the latter is stacked in too moist a condition it is apt to become what is known as mow burn. Especially is this the case with barleys containing large percentages of nitrogen and of high enzymatic activities. Such barleys are denoted "warm" by M. Delbrück from their tendency to heat when stored in a moist condition. The effect of this heating is exhibited in the grains becoming black and discoloured at the tips; they are then said to be milled. Even in an otherwise dry season a large amount of rain during harvest causes the corns to become "weathered," whilst some of them begin germinating and rot. At the same time heavy dews at night whilst the barley lies cut in the field, or even a sprinkling of rain, assists in mellowing the grain, which often in consequence works the more freely on the malting floors. Properly harvested barley is all the better for remaining in stack for two or three months, as was the practice in former years; if, however, it has been stacked too wet the sooner it is broken down the better.

It is difficult to give any specific test for ripeness, but a series of observations has been made by H. T. Brown and F. Escombe. Samples of barley were taken from the field on the 20th, 24th, and 29th of July, and on the 2nd, 6th and 10th of August, and preserved in spirit so that they remained in the same state as when they were gathered. Sections were then cut of these corns, when it was found that the progress of ripening is attended by deformation and ultimate disintegration of the cell nucleus. This change is denoted by the term nuclear senescence is said to begin in the starch-containing cells, near the periphery of the corn, immediately underlying the layer next to the albumen. This disintegration is accompanied by a complete destituation of the nucleus, and at the end of seven or eight days nearly the whole of the endosperm has been involved. Brown and Escombe state that when this nuclear test is properly applied it stumps as immature those corns in a sample which are uniformly and constantly good, and as ripe as those in which the ratio of nitrogen to carbohydrate is unduly high, owing to an excess of nitrogenous manure in the soil, or to sparser sowing with its consequent reduction of root competition. This method, interesting though it be, is not fitted for practical use, and the agriculturist must rely as heretofore upon empirical methods for deciding whether or not the grain has attained ripeness or maturity.

True seed weight is a useful criterion in arriving at an opinion regarding the value of a sample of barley; but in basing judgment upon this factor regard must be paid to the fact already mentioned that if the grains be dressed closely the bushel weight is increased. The reason of this is that with the removal of the outer layers the pack more closely together. The best British malting barleys should weigh 52–56 lb per bushel, the standard weight for malting barleys being 56 lb.

During the storage of barley access of air is necessary, otherwise the grain dies from asphyxiation. Sound barley after being kiln-dried retains its vitality for a number of years; but the statement that the corns found in the Egyptian mummy cases, in which they had remained for several thousands of years, were still capable of germination, is contrary to modern experience. Moisture must also be carefully excluded, as it initiates germination in a few cells only of the endosperm and causes heating. A constant repetition of wetting such as may take place on account of alterations of the atmospheric temperature, which causes moisture to be deposited, in the form of dew, may ultimately destroy the vitality and foster the growth of the disease which develops on broken and damaged corns. In this connexion the advantage of screening and sweating of barley before storing it will be apparent (see below).

An immense amount of damage is caused to the grain, during storage, by various insects, one of the most destructive of these being the common weevil (Calandra granaria). When fully developed this insect measures 3/4 to 3/8 of an inch in length, and is of a bright chestnut colour. The larvae are fleshly legless grubs, shorter than the adults, and are usually white, with a series of purplish lines along the body; the head is round with strong jaws. The pupa is white, clear and transparent, showing the form of the future weevil. The female bores a hole in the grain with her snout and deposits an egg. The larva is white and legless, and when the adults emerge the larva goes its changes therein. Windisch asserts that only barley which has ripened in the granary is attacked by weevil. Grain which is only slightly attacked should be kilned at a temperature of 122° F., which destroys the weevil in all stages of development. To detect weevil in a sample of barley, the grain should be spread out on a sheet of white paper in bright sunlight. If weevils are present they soon appear, and betake themselves to a position outside the sunlight, to which they are averse. Treatment of the grain with carbon...
bisulphide has been suggested as a means of destroying weevil; even if efficacious, however, such a process could not be recommended on account of its danger, carbon bisulphide being highly inflammable. The only practical means of ridding a granary or shop of weevil is to clear out all the grain and leave it empty for a year or more.

The vitality of barley may be determined by causing a sample to germinate in any of the well-known forms of apparatus devised for that purpose, and counting the percentage of germinating and idle corns. The germinative capacity of a sample of barley may frequently be raised by sweating (see below), which, as already mentioned, brings about a kind of artificial maturation.

**Malting.**—There are two systems of malting used in England: floor malting and pneumatic or drum malting. These systems will be described separately.

A floor malting consists of a rectangular building of several storeys, having the cisterns at one end and the kilns at the other. The uppermost floor is devoted to barley.

![Diagram of 200 quarter malting at Mortlake](image)

Figure 8 shows a longitudinal section of Messrs Watney, Combe, Reid & Co.'s 200 quarter malting at Mortlake. The barley is carried to the top of the building by the elevator A, where the screening and dressing machinery is situated. After leaving these machines the grain is conveyed on bands to the barley floors B and C. The floor C contains also the steeping cisterns. The six working floors are D, E, F, G, H, K. The floors are ventilated by louvres, N, N, N. The cisterns are connected to the floors by means of plugs. The "pieces," as they are termed, of germinating barley are gradually worked along the floors to the kilns M, M, on to which they are loaded by rotary bands. The fire-places O, O, are arranged so that the draught may be easily controlled. The hot air and products of combustion pass up the shafts P, P, to the hot-air chamber R, R, where they strike the baffle plates S, S. These plates disperse the hot air and cause evenly beneath the kiln floors T, T. through the green malt. After drying and curing, the malt is allowed to cool and is then carried by bands to the floor U, where by suitable machinery the coombs or rootlets are removed. The finished malt is stored in the bins V, V, V.

On arrival at the malting the barley has to be put through the following operations seriatim: receiving, hoisting and weighing, rough screening, drying and sweating, storing until required for use, screening, grading and removing broken corns, steeping, couching, flooring, withering, drying and curing, dressing and polishing, storing, weighing, sacking and discharging the finished malt.

In sweating barley the temperature should not be allowed to rise above 120° F.; it is usually conducted at 100° F.; and subsequently the barley should be stored for some weeks before it is steeped.

The capacity of a malting is described by the number of quarters which are put through it every four days. A fifty quarter malting does not merely mean that the cisterns have a capacity of fifty quarters, but that this quantity of barley goes through the house every four days. The average time the germinating barley is on the floors is twelve days, and, as a rule, kilning occupies four days. If, as sometimes happens, the malt has to be kept on the floors thirteen, fourteen, fifteen days, or even longer, the malting is not being worked at the capacity under which it is described, and the kilns may remain unused for a day or more. Conversely, when the malt is loaded at less than twelve days, a day or two has to be missed in steeping. In the former case when the kilns are not being used for drying and curing malt, advantage may be taken to utilize them for sweating barley.

Steeping cisterns were formerly rectangular vessels, of slate, brick or cement, from which the barley had to be discharged by shovelling it out. The forms approved most at the present day are conical and constructed of iron; they have arrangements at the apex of the cone, the lower portion, for discharging the grain by gravitation. The steeping period ranges from 48 to 70 hours; it varies according to the kind of barley, and the time of the year. In some of the older maltings there are no arrangements for heating the steep water, and in the winter steeping has occasionally to be performed with water at a temperature near its freezing-point. Steeping should be carried out at a temperature as near as possible to 55° and not higher than 60° F. The usual practice is to fill the cistern up to a certain height with water and throw the barley into it, stirring it until it is about level; the heavy corns will then sink directly to the bottom, whilst the light corns and refuse float on the surface and may be skimmed off. During the time the barley remains in the cistern it is usual to change the steep water two or three times, generally at intervals of twelve hours or tides. The advantage of this is not merely to keep the grain fresh and sweet, but to bring it into contact with the air during the time it is taking up water. Aération of the steep has long been recognized in Germany as promoting germination, and several arrangements are on the market enabling air to be passed through the grain while it is in the cistern. It has been recommended by Graham, Stopes, Moritz and Morris, and experimental evidence as to its beneficial effects has been published by Windisch, Bleisch, Will, and Baker and Dick. When the corn is steep ripe it contains some 60% of water. Steeping does not consist, however, merely in the
imbibition of a certain amount of water; in order to bring about germination this water must remain within the corn a certain length of time. Thus, although it is quite possible to force the necessary amount of water into the grain in less than the 48-70 hours usually taken up by the steeping process, the grain is not steep-wise even when certain changes initiated by the water have taken place, and these require time for their completion. The following average data are useful to remember in connexion with the steeping process:

- Amount of water in steep-ripe barley (about) 60%.
- Matter removed from barley during steeping: 1.5%.
- Increase in volume of barley due to water absorption (about) 18-20%.

There has been much discussion as to the influence of saline matters in water on the steeping process. The late Professor Lintner stated that the common saying was: "A full bushel of barley stirs 16 gal of water", but this was disputed by Mills and Pettigrew who found that waters containing calcium salts extracted a minimum of nitrogenous compounds from the barley; they also came to the conclusion that the esteem in which the Lichfield water is held for steeping purposes is due to the presence of nitrates which, they assert, have a stimulating effect on the subsequent germination of the grain. The writer has added lime-water to the extent of one-third per cent of water in barley and did not observe it to promote regularity of germination. Bearing in mind, however, the observations of Adrian J. Brown, that the barley corn is enclosed in a membrane permeable to water but impermeable to most salts, it is possible that the saline components of water may have any effect except in removing matter from the external portions of the grain and on those corns which are broken. The apparent beneficial effect of lime-water in the steep is probably entirely due to the removal of matters from the husks or paleae.

Malting floors may be constructed of cement, tiles or slate, the two former being preferable to the latter. Ford, in 1849, recommended 200 sq. ft. per quarter of barley steeped as the area of the working floors, and he was quite convinced of the necessity of allowing ample floor room, so that the grain could be worked on the slow, cool system. Subsequently, however, maltsters reduced their floor area, and put the grain rapidly through the malting, thus producing what is termed "forced" malt. This kind of malt was, however, condemned by practical brewers, and a chemical test whereby forcing could be detected having been devised by E. R. Moritz and G. H. Morris, maltsters have been compelled again to increase the area of their working floors. At the present time the approved area may be placed at 750-200 sq. ft. per quarter of barley steeped. The area is, however, largely ruled by the kind of barley to be malted.

After the barley has been thrown out of the cistern it is made up in a rectangular heap 15-20 in. deep, called the "couch"; the object of this is to enable it to gather heat and so start germination. It usually remains in couch for 12-24 hours, until in fact the interior portion of the heap registers a temperature of about 60°F. During the days of the malt tax the exciseman gauged the quantity of the barley while it was in the couch. After coughing the barley is spread thinly and evenly on the floor, forming what is known as the young floor or No. 1 piece. The first visible sign of germination is the sprouting of the rootlet, termed "chitting," and this occurs either while the grain is on the couch or on the young floor. As already mentioned, it may be quickened by aerating the grain in the cistern. From the time the barley is first cast out of the cistern up to the stage of the young floor, or No. 1 piece, it has a pleasant ethereal odour resembling apples. Drs Thomson, Hope and Coventry stated in the earlier part of the 19th century that they distilled "spirits" from germinating barley at this stage. In the light of our present knowledge it would not be surprising if alcoholic fermentation were proved to occur within the grain at this stage, since intramolecular or anaerobic respiration in certain vegetables has been found to be due to alcoholic fermentation.

The thickness at which the young floor is spread depends upon the outside temperature and the nature of the barley. If the weather be warm, or if there be a tendency for the barley to heat, the piece must be spread all the thinner. At this stage the grain loses its external wet appearance. When spread too thickly the grain will begin to sweat, and the rootlets will be thrown out suddenly and unevenly. As a rule, under these circumstances, the rootlets will be long and thin, when they are said to be "wild." A piece which has been allowed to get into this condition must at once be spread thinner. If the sweating has not continued long, the harm done may be confined to increased loss by respiration. The young floor is usually turned with a plough twice during twelve hours, and it may be forked between whiles, but no hard and fast rule can be laid down as to when this is necessary; it must be left to the maltster's judgment, as it depends entirely on what is going on within the grain. The object of turning is in the first place to aerate the grain and freshen it, secondly to check excessive rise of temperature, and thirdly to promote evenness of growth. Too frequent turning is not to be advised. After remaining four days on the young floor three or four rootlets should have appeared, and the acrospire should have begun to grow up the back of the corn. The apple-like odour of the piece then prevails, with additional growth of that of the common rush, and this should continue the whole time that the malt remains on the floor. On the fifth day the piece is next moved to No. 2 position, a stage nearer the kiln. It is here that sprinkling is resorted to when necessary. The amount of sprinkling and the time it is given cannot be exactly prescribed. The amount may vary from two to five gallons per quarter, and it should only be given when the rootlets, which ought to be short and curly, and five or more in number, show signs of losing their freshness. If an excessive amount of sprinkling be given forced growth ensues. It is preferable not to add the whole of the water at one time, but to divide it over two lots; and immediately after the piece has been sprinkled it should be thoroughly and carefully mixed, otherwise some of the grain will receive an undue proportion of water. When all the sprinkling water has been given to the piece, which as a rule should not be done later than at the beginning of the 3rd month of flooring, the temperature should be kept down to about 55°F. by turning.

Too frequent turning may, however, detach the rootlet, and it may cause the grain to lose its vitality prematurely, so that growth of the acrospire stops.

By about the eighth day of flooring the acrospire should be about three-quarters up the corn. After this the germinating corn is moved forward to No. 3 piece, which is at first spread as thinly on the floors as in the previous pieces. Here it gradually dries and incipient withering of the rootlets sets in. The only treatment which is now given to the grain is to heap it up thicker and thicker by degrees until it is ready for loading on the kiln. This increase in thickness of the piece (now called the old piece) should not be too sudden, especially if the grain be fresh in appearance and contain a large quantity of water. When the piece is thickened up to say 10 in. in depth, while it is in a very moist condition, heating and sweating take place, with additional growth of acrospire and rootlet. Under such forcing conditions a large production of sugar and degradation of the proteins will take place. When, however, the moisture has been gradually reduced before thickening up, the rootlet dies off, and although increase of temperature may occur, this is accompanied by little or no further growth of the acrospire, action being confined to the mellowing of the grain by the enzymes. When the malt is ready for loading on the kiln it should be possible to break down the contents of each corn between the thumb and finger. Opinions differ as to what the final temperature on the withering floor should be. If the moisture content of the malt be about 50%, the piece must be kept thin to avoid sweating. But under these conditions mellowing does not occur, hence the necessity of reducing the moisture content gradually after the sprinkling water has been given. When the process has been conducted properly, in which the piece may be allowed to rise as high as 70°F. during the six hours previous to loading. The moisture content of the green malt when loaded should not be much above 40%.

The endospem of green malt which is ready for the kiln should be soft and mealy, and should not exude moisture when
pressed between the thumb-nails, but should crumble and disintegrate to a chalky mass having little or no adhesiveness.

The foregoing observations are not to be regarded as hard and fast rules, but they are simply intended to give some indications of the malting process when it proceeds on normal lines; it may be that on account of the presence of damaged corns the piece begins to develop much by abstinence the next day, and it then has to be kept thin and sometimes even loaded on to the kiln prematurely.

The malt made for grain distillers, in which a high diastatic activity is required, is manufactured on quite different lines from those above indicated. It is often sprinkled late, and loaded on kiln often in a sodden condition. In some cases sprinkling on kiln is resorted to, but it is doubtful if this leads to the desired object. Other things being equal, the smaller the corns—i.e. the greater number of embryos in a given weight—the higher the diastatic activity of the malt. In selecting a barley for the production of highly diastatic malt, the diastatic power of the original raw grain is a factor of great importance.

**Kilning.**—When loaded on kiln, malt intended for brewing ale and stout is, if properly withered, in a moribund condition; nevertheless, during the first stages of the kilning process a certain amount of vital activity is manifested, and the malt undergoes mellowing by the action of enzymes on the contents of the endosperm. If the malt be loaded while the rootlets appear fresh on account of the presence of too much moisture, rapid growth of the acrospire ensues, giving rise to overshot corns, known in Germany as "husser." To check this the moisture must be rapidly reduced by passage of large volumes of air through the malt. But under such circumstances mellowing does not occur. The ideal conditions of kilning are when the malt has been properly withered on the floors before loading, and, assuming that drying and curing occupy four days, that 25–30% of the moisture be removed very gradually, this occupying the first three days, at the end of which the malt is said to be hand-dry. The thickness at which the malt is spread on the kiln should not exceed 7–8 in., and until hand-dry (that is to say, reduced to a moisture content of 12–15%) it should not be turned; if moved at all (and that only is necessary when reek occurs), it should only be lightly forked. The rate at which the temperature is raised depends largely on the kind of malt to be made and the construction of the kiln. If high flavour and colour are required, these are produced by keeping the malt for several hours near a temperature of 160°F, while it still contains 12–15% of moisture. If more than this amount of moisture be present when the temperature reaches the limit just mentioned, the drying process is frequently accompanied by the result that "forced" malt would be produced. A certain amount of colour is produced at the final temperature to which the malt is raised; but when such means are relied upon for the production of the greater part of the colour, reduction of extract and deficiency of flavour follow, the colour being then almost exclusively the result of caramelization of the carbohydrates.

The so-called curing stage constitutes the last part of the kilning process, and the malt must then be turned frequently to ensure uniformity of action. Mechanical turners are exceedingly useful for this purpose. Curing in a drum, as in the so-called pneumatic malting process (see below), also effects satisfactory curing.

The following table will give an idea of the kilning temperatures usually employed for the three kinds of malt mentioned, but it must be understood that these temperatures are largely regulated by the construction of the kiln and the amount of draught available. In this connexion it may be mentioned that the final curing temperature is not necessarily a criterion of the tint of the malt. A malt may have been finished off at a very high temperature and still be a pale malt provided the moisture percentage has been sufficiently reduced in the initial stages of kilning.

**Metabolic Changes.**—All through the malting process metabolic changes are proceeding, in which both carbohydrates and proteins are concerned. In its resting stage the embryo of a barley-corn is generally free from starch; as soon as germination sets in, however, starch appears in the scutellum, while the amount of protein is reduced by a progressive formation from maltose originating on the action of diastase on the starch of the endosperm. Sucrose also augments in the aleurone layer, but starch is never formed in the aleurone cells. These changes occur when the malt is first loaded on kiln; indeed, at no part of the malting process is there greater physiological activity.

Kilning has been specially studied by J. Grüss, who divides the process into four stages, the first being that at which the temperature limit is 113°F. It is characterized by a continuation of the living processes, especially growth of the acrospire, which, as already stated, proceeds too far if the malt be loaded too wet. In any case the rootlet dies away. The metabolism of the carbohydrates already mentioned is accompanied by that of the nitrogenous constituents, the reserve protein of the sub-aleurone layer being attacked by proteolytic enzymes and broken down into simpler compounds. This is a most important matter from the point of view of the brewing value of barley, for the degradation products of the proteins are necessary constituents of wort as yeast food. Moreover, unless proper modification of these protein bodies occurs it is impossible to produce tender malt. A barley which contains a high percentage of reserve protein is as a rule unfitted for malting purposes, and indeed, the higher the protein content the greater the difficulty the maltster experiences in dealing with it. Protein hydrolysis requires the presence of a certain amount of moisture, and if this be removed too rapidly by a forced draught at the early stages of kilning the proteolytic enzymes cannot perform their function. If, on the other hand, the grain be loaded in too moist a condition, and the temperature be raised too quickly, the proteolytic enzymes lose their activity and the proteins remain for the most part unattacked. When germination is allowed to proceed on the kiln too great degradation of the protein occurs, and the malt is liable to produce fruity beers, on account of the presence of an excessive amount of nitrogenous nutritive matter, which leads to the development of disease organisms.

The second stage of the kilning process, according to Grüss, is that at which the temperatures range from 113°F to 167°F. The life of the corn is now suspended, but enzymic processes continue. The starch is further saccharified, and the dividing line of the aleurone layer at the furrow is attacked, as are also the cell walls of the endosperm, which are still intact, these being partially converted into gummy substances. This change, however, also requires the presence of a certain amount of moisture. If too much air be passed through the malt at this stage the above-named dividing partition of the cell walls is not attacked. The air may expand the grain to some extent and produce malt of a low bushel weight, which, however, is not properly modified and cannot give satisfactory results in practice.

During the third stage of kilning, an enzyme, which Grüss claims to have recognized, and which he denotes spermoxidase, is said to exert its activity.

Schönfeld has confirmed the discoveries of Grüss by practical experiments.

**Fuel.**—The fuel used for drying and curing malt is either anthracite or coke, and the greatest care is necessary in selecting it on account of its liability to contain arsenic, which is to a greater or less extent an invariable constituent of all coal. The fuel used for malting purposes should not contain more arsenic than 4 grain per lb. Gas coke should on no account be used, unless it has been confirmed—

</table>
proved to be sufficiently free from arsenic; but the best oven coke frequently contains so little arsenic that it may be employed with perfect safety, especially if it be mixed with a proportion (e.g. 5%) of milk of lime, which retains the arsenic as calcium arsenate. In Germany malt is, as a rule, dried and cured with hot air, whilst in Great Britain the products of combustion are passed through the malt, as it is believed that they exert a beneficial influence on the flavour. The proportion of fuel used for drying and curing malt varies according to the quality of the fuel and the construction of the kiln, but on an average it may be placed at 50-80 lb per quarter.

Storing.—After the malt has passed through the curing stage it is generally heaped up for a few hours. This is believed to increase its flavour. The malt is then stripped from the kiln, and the rootlets, technically known as the coombs, are removed. Formerly this was effected by workmen treading the malt, who wore heavy boots for the purpose. At the present time, however, the rootlets are usually removed by machinery, special forms of which have been devised for this as well as for dressing and polishing the malt. It is the custom of some maltsters to store malt with the rootlets still attached; but this is an objectionable practice, since malt coombs attract moisture, and the presence of more than 3% of moisture in malt produces the condition known as "slackness." When the malt is packed in bin it is often covered with a layer of coombs, which then prevent access of atmospheric moisture. Malt, to preserve its good qualities intact, should be stored in bins made as nearly as possible air-tight, and it should never be placed in bin until it is quite cool. It is probably wrong to store malt in bins adjacent to the kilns, where it is kept at a higher temperature than that of the surrounding atmosphere. During storage of the malt a kind of mellowing occurs, the mechanism of which is not understood. It is, however, known by practical brewers that the best results cannot be obtained when new malt is used.

Premature Malting.—Several years ago Galland suggested germinating barley in a drum, in his idea being to do away with handling of the grain, and also to be independent of changes of atmospheric temperature. The latest development of this system, the so-called Galland-Henning process of pneumatic malting, has been improved by Mr. R. Blair Robertson, and a diagrammatic view of the interior of one of these maltings, showing the drums and conical steeping cisterns, is shown in Fig. 9.

The drums are provided with a perforated channel for the passage of air through the malt, which is packed in the annular space between this channel and outside wall of the drum. Each drum is capable of revolving on its axis, and there are arrangements for passing either moist, saturated or dry air through the malt. The system as now improved is capable of producing some of the best malt, especially if, after germination, has been completed in the drums, measured exclusively by volume, it frequently happens that a given number of quarters of barley yields a number of quarters of finished malt. When this happens it is usual to speak of an increase having been obtained. At the present time weight replaces measure for both barley and malt, and although it is usual to speak of the quantity of grain in terms of quarters, what is meant is not the measured quarter, but so many weighed standard quarters. The standard quarter for English malting barley is 44 lb and for malt 336 lb. From this it will be seen that when a given number of weighed quarters of barley yields the same number of quarters of finished malt, the actual yield is 75% and there is then said to be neither increase nor decrease. As a rule, in practical working the yield of malt varies from a 4% decrease to a 10% increase, corresponding to an actual yield on the original barley of 72 to 82.5%.

Fig. 9.—Diagrammatic view of pneumatic malting, showing pneumatic washing and steeping cisterns.
to the truth. Instead of counting the corns by hand, an instrument may be used for this purpose.

If 1000 corns of a barley were found to weigh 42 grammes, and 1000 corns of a finished malt from the same barley 32 grammes, then the yield of malt is \( \frac{32 \times 100}{42} = 76.1 \), this corresponding to a 1% increase. Assuming that the moisture content of the barley was 15% and that of the finished malt 2%, 1000 grammes of malt will contain 2 grammes of moisture, and 76-1 grammes will contain 76-1 - 1.5 = 74.6 grammes of dry matter. This was obtained from 100 - 15 = 85 grammes of barley dry substance.

Hence 100 parts of barley dry substance will yield 72-6 \( \times \) 100 = 87.7 grammes of malt with corresponding to a loss of dry substance equal to 12.5% of the dry substance of barley, or with a loss of 10.7% on the barley containing 15% of moisture.

The results obtained by this method of laboratory control when it is accurately carried out agree very closely with those deduced from the practical results of weighing the barley, malt and coombs in the malting.

Special Malts.—In addition to the kinds of malt considered in what precedes, there are others mostly used for imparting specific flavors to special sorts of beer and stout. These are crystal malt, imperial malt, brown or blister malt, and black or roasted malt.

Crystal malt is grown for a shortened period on the floors, and then placed in a wire cylinder, which is rotated over a fire so that it is dried at an elevated temperature, so that it is passed from 250 to 280 lb. Imperial malt is dried off on an ordinary kiln at a final temperature of 240–270°C, but it is not allowed the usual length of time on the withering fire. It is placed on the dry kiln in a layer and roasted up to 12.5% of the weight. The roasted malt is then allowed to cool and the heat from burnt wood is first applied until the bulk of the moisture has been driven off, when the temperature is suddenly raised so that the grains swell some 25% and the malt takes up a strong empyreumatic flavour from the products of combustion. This kind of malt weighs 270–300 lb per quarter. Black or roasted malt is prepared by roasting malt in a cylinder. Ford states that perfectly malted corn gives a colour of less intensity and permanence than does partially roasted malt. This has been observed in this laboratory.

A certain quality of the so-called black malt is actually made from raw barley, but this gives a product of inferior flavour. The weight per quarter of black malt varies as much as from 212 to 290 lb. The following determinations are usually carried out: Extract per standard quarter, moisture, diastatic activity by the Lintner process, tint, and matters soluble in cold water. The physical examination of malt is also a matter of importance, inasmuch as direct evidence is obtained thereby of the modification of the malt. Among the methods adopted for this purpose may be mentioned counting the percentage of corns in which the aspera has grown up to one-half, two-thirds and three-fourths of the length of the corn. The diastase content and the modification of the endospERM should proceed pari passu with the growth of the aspera. The sinker test is also useful when carried out in an intelligent manner. Those corns which sink in water and which float in alcohol are more suitable, as the gravity less than water and the corns have equal density throughout; consequently they float horizontally in water. In forced samples the proximal ends are frequently lighter than the distal ends, and the corns float horizontally in water. The latter, however, may in some cases fill with water, and the corns lie flat or sink. This is a characteristic of over-modified malt. It will be seen from these remarks that it is essential to carry out the einkorn under standard conditions. The modifications of the malt may also be determined by means of the diaphanoscope already referred to under Barley.

MALTA, the largest of the Maltese Islands, situated between Europe and Africa, in the central channel which connects the eastern and western basins of the Mediterranean Sea. The group belongs to the British Empire. It extends over 29 m., and consists of Malta, 91 sq. m., Gozo (q.v.) 20 sq. m., Comino (set apart as a quarantine station) 1 sq. m., and the uninhabited rocks called Cominotto and Fliira. Malta (lat. of Valletta Observatory 35° 53' 55" N., long. 14° 30' 45" W.) is about 60 m. from the nearest point of Sicily, 140 m. from the mainland of Europe and 180 from Africa; it has a magnificent natural harbour. From the dawn of maritime trade its possession has been considered so important to the strongest nations on the sea for the time being.

Malta is about 170 m. long by 83 broad; Gozo is 82 by 43 m. This island stretches from N.E. to S.E. On the S.W. the declivities towards the sea are steep, and in places rise abruptly some 400 ft. from deep water. The general slope of these ridges is towards the N.W., facing Sicily and snow-capped Etna, the source of cool evening breezes. The Birmenga range, rising 726 ft., is nearly at right angles to the axis of the main island.

The geological “Great Fault” stretches from sea to sea at the foot of these hills. There are good anchorages in the channels between Gozo and Comino, and between Comino and Malta. In addition to the harbours of Valletta, there are in Malta, facing N.W., the bays called Mellieha and St. Paul’s, the inlets of the Salina, of Madalena, of St. Julian and St. Thomas; on the S.E. there is the large bay of Marsa Scirocco. There are landing places on the S.W. at Fombil-rh and Miggarro. Mount Scabberas (on which Valletta is built) is a precipitous promontory about 1 m. long, pointing N.E. It rises out of deep water; well-sheltered creeks indent the opposite shores on both sides.

The waters on the S.E. form the “Grand Harbour,” having a narrow entrance between Ricasoli Point and Fort St Elmo. The series of bays to the N.W., approached between the points of Tigne and St Elmo, is known as the Marsamuscetto (or Quarantine) Harbour.

Mighty fortifications and harbour works have assisted to make this ideal situation an emporium of Mediterranean trade. During the Napoleonic wars and the Crimean campaign the Grand Harbour was frequently overcrowded with shipping. The gradual supplanting of sail by steamships has made Malta a coasting station of primary importance. But the tendency to greater light and soundings, and the reduction of the responsibilities of those responsible for the civil administration towards the end of the 19th century to realize that the harbour accommodation was becoming inadequate for modern fleets and first-class liners. A breakwater was therefore planned on the Monarch shoal, to double the available anchorage area and increase the frontage of deep-water wharves available in all weathers.

The Maltese Islands consist largely of Tertiary Limestone, with somewhat variable beds of Crystalline Sandstone, Greensand and Marl or Blue Clay. The series appears to be in line with similar formations at Tripoli in Africa, Cagliari in Sardinia, and to the east of Marseilles.

To the south-east of the Great Fault (already mentioned) the beds are more regular, comprising, in descending order, (a) Upper Coralline Limestone; (b) Yellow, Black or Greensand; (c) Marl or Blue Clay; and (d) White, the semipale Nello, called those; (e) Cholote late nodules with shells, &c.; (f) Yellow Sandstone; (g) Lower Crystalline Limestone. The Lower Limestone probably belongs to the Togarian stage of the Oligocene series, and the Upper to the Coralline stage of the Lower Miocene. The beds are not folded.

The general dip of the strata is from W.S.W. to E.N.E. North of the Great Fault and at Comino the level of the beds is about 400 ft. lower, bringing (c), the Marl, in contact with (d) and (e), the Nello. In the latter part of the Lower Miocene.

The beds are not folded. The general dip of the strata is from W.S.W. to E.N.E. North of the Great Fault and at Comino the level of the beds is about 400 ft. lower, bringing (c), the Marl, in contact with (d) and (e), the Nello. In the latter part of the Lower Miocene.

Malta has several species of zoophytes, sponges, mollusca and crustacea. Insect life is represented by plant-bugs, locusts, crickets, grasshoppers, cockroaches, dragon-flies, butterflies, numerous varieties of moths, bees and mosquitoes.

Among the fish may be mentioned the tunny, dolphin, mackerel, sardine, sea-bream, dentice and pagnell; wrasse, of exquisite rainbow hue and good for food; members of the herring family, sardines, anchovies, flying-fish, sea-pike; a few representatives of the cod family, and some flat fish; soles (very rare). Cernus which grows to large size, several species of grey and red mullet; eleven species of Triglidae, including the beautiful flying gurnard whose colours rival the angel-fish of the West Indies; and eighteen species of mackerel, all migratory.

The real population of Malta, viz. of the country districts, is to be differentiated from the cosmopolitan fringe of the cities. There is continuous historical evidence that Malta remains to-day what Diodorus Siculus described it in and 1st century, "a colony of the Phoenicians.

This branch of the Caucasian race came down the great rivers to the Persian Gulf and thence to Palestine. It carried the art of navigation through the Mediterranean, along the Atlantic seaboard as far as Great Britain, leaving colonies along its path. In prehistoric times one of these colonies displaced previous inhabitants of Libyan origin. The similarity of the megalithic temples of Malta and of Stonehenge connect along the shores of western Europe the earliest evidence of Phoenician civilization. Philology proves that, though called "Canaanites" from having sojourned in that land, the Phoenicians have no racial connexion with the African descendants of Ham. No subsequent invader of Malta attempted to displace the Phoenician race in the country districts. The Carthaginians governed settlements of kindred races with a light hand; the Romans took over the Maltese as "decontents," not as a conquered race. Their conversion by St Paul added difference of religion to the causes which prevented mixture of race. The Arabs from Sicily came to eject the Byzantine garrison; they treated the Maltese as friends, and were not sufficiently numerous to colonize. The Normans came as fellow-Christians and deliverers; they found very few Arabs in Malta.

The fallacy that Maltese is a dialect of Arabic has been luminously disproved by A. E. Caruana, Sull' origine della lingua Maltese.

The upper classes have Norman, Spanish and Italian origin. The knights of St John of Jerusalem, commonly called "of Malta," were drawn from the nobility of Catholic Europe. They took vows of celibacy, but they frequently gave refuge in Malta to relatives driven to seek asylum from feudal wars and disturbances in their own lands. At the British occupation there were about two dozen families bearing titles of nobility granted.
or recognised by the Grand Masters, and descending by primogeniture. These "privileges" were guaranteed, together with the right of religion of the islanders, when they became British subjects, but no government has ever recognised papal titles in Malta. High and low, all speak among themselves the Phoenician Maltese, altogether different from the Italian language; Italian was only spoken by 13-24% in 1901. Such Italian as is spoken by the lingering minority has marked divergences of pronunciation and inflexion from the language of Rome and Florence. In 1901, in addition to visitors and the naval and military forces, 18,022 Maltese spoke English, and the number has been rapidly increasing.

In appearance the Maltese are a handsome, well-formed race, about the middle height, and well set up; they have escaped the negrooid contamination noticeable in Sicily, and their features are less dark than the southern Italians. The women are generally smaller than the men, with black eyes, fine hair and graceful carriage. They are a thrifty and industrious people, prolific and devoted to their offspring, good-humoured, quick-tempered and impressionable. The food of the working classes is principally bread, wine, oil, mutton, vegetables, tea, coffee, but not from Malta; common wine is largely imported from southern Europe. The Maltese are strict adherents to the Roman Catholic religion, and enthusiastic observers of festivals, fasts and ceremonies.

In 1906 the birth-rate was 40-68 per thousand, and the excess of births over deaths 2637. In April 1907 the estimated population was 206,690 of whom 21,911 were in Gozo. This phenomenal congestion of population gives interest to records of its growth; in the 10th century there were 16,767 inhabitants in Malta and 4514 in Gozo; the total population in 1514 was 22,000. Estimates made at the arrival of the knights (1530) varied from 15,000 to 25,000: it was then necessary to import annually 10,000 quarters of grain from Sicily. The population in 1557 was, Malta 24,000, Gozo 7000. In 1582, 20,000 quarters of imported grain were required to avert famine. A census of 1590 makes the population 35,500; in that year 3000 died of want. The numbers rose in 1601 to 33,000; in 1614 to 41,084; in 1632 to 50,113; in 1667 to 55,155; in 1677 11,000 are said to have died of plague out of the total population. At the end of the rule of the knights (1798) the population was estimated at 100,000; sickness, famine and emigration during the blockade of the French in Valletta probably reduced the inhabitants to 80,000. In 1829 the population was 114,230; in 1836, 119,878 (inclusive of the garrison); in 1873, 145,605; at the census in 1901 the civil population was 184,724. Sanitation decreases the death-rate, religion keeps up the birth-rate. Nothing is done to promote emigration or to introduce manufactures.

Towns and Villages.—The capital is named after its founder, the Grand Master de la Valette, but from its foundation it has been called Valletta (pop. 1901, 24,685); it contains the palaces of the Grand Masters, the magnificent Auberges of the several "Languages" of the Order, the unique cathedral of St John with the tombs of the Knights and magnificent tapestries and marble work; a fine opera house; and its walls are conspicuous. Between the inner fortifications of Valletta and the outer works, across the neck of the peninsula, is the suburb of Floriana (pop. 2728). To the southeast of Valletta, at the other side of the Grand Harbour, are the cities of Senglea (pop. 1893), Vittoriosa (pop. 1351) and Cospicua (pop. 12,184); this group is often spoken of as "The Three Cities." The old capital, near the centre of the island is variously called Notabile, Città Vecchia (q.v.), and Medina, with its suburb Rabat, it is the old core of the island, and has been described as the catacombs and the ancient cathedral of Malta. Across the Marsamxett Harbour of Valletta is a considerable modern town called Sliema. The villages of Malta are Mellieha, St Paul's Bay, Musta, Birrhicara, Lija, Attard, Naxxar, Gharb, Misrada, S. Julian's, S. Giuseppe, Dingli, Zebank, Siegfried, Curtor, Carzei, Zurriko, Crend, Micayawia, Cirkew, Zabbar, Asiel, Zejtun, Gudia and Marsa Scirocco. The chief town of Gozo is called Victoria, and there are several small villages.

Industry and Trade.—The area under cultivation in 1906 was 41,534 acres. As a rule the tillers of the soil live away from their lands, in some neighbouring village. The fields are small and composed of terraces by which the soil has been worked up along the contours of the hills, with enormous labour, to save it from being washed away. Viewed from the sea, the top of one wall just appearing above the next produces a barren effect; but the aspect of the land from a hill in early spring is a beautiful contrast of luxuriant verdure. It is estimated that there are about 10,000 small holdings averaging about four acres and intensely cultivated. The grain crops are maize, wheat and barley; the two latter are frequently sown together. In 1906, 13,000 acres produced 17,975 quarters of wheat and 12,000 quarters of barley. The principal fodder crops are green barley and a tall clover called "sulla" (Hedyera coronarium), having a beautiful purple blossom. Vegetables of all sorts are easily grown, and a rotation of these is raised on land irrigated from wells and springs. Potatoes and onions are grown for exportation at seasons when they are scarce in northern Europe. The rent of average land is about £2 an acre, of very good land over £3; favoured spots, irrigated from running springs, are worth up to £12 an acre. Two, and often three, crops are raised in the year; on irrigated land more than twice as manycroppings are possible. The presence of phosphates accounts for the fertility of a shallow soil. There is a considerable area under vines, but it is generally much cheaper to buy viti from Sicily. The Maltese have, however, the greatest West India market for their wine. Some of the best oranges in the world are grown, and exported; but sufficient care is not taken to keep down insect pests, and to replace old trees. Figs, apricots, nectarines and peaches grow to perfection. Some cotton is raised as a rotation crop, but no care is taken to improve the quality. The carob tree and the prickly pear are extensively cultivated. There are exceptionally fine breeds of cattle, asses and goats; cows of a large and very powerful build are used for ploughing. The supply of butchers' meat has to be kept up by constant importations. More than two-thirds of the wheat comes from abroad; fish, vegetables and fruit are also imported from Sicily in considerable quantities. Excellent honey is produced in Malta; at certain seasons funny-fish and young dolphin (lampcu) are abundant; other varieties of fish are caught all the year round.

About 3000 women and children are engaged in producing Maltese lace. The weaving of cotton by hand-looms survives as a languishing industry. Pottery is manufactured on a small scale; ornamental carvings are made in Maltese stone and exported to a limited extent. The principal resources of Malta are derived from its being an important military station and the headquarters of the Mediterranean fleet. There are great naval docks, refitting yards, magazines and stores on the south-east side of the Grand Harbour; small vessels of war have also been built here. Steamers of several lines call regularly, and there is a daily mail to Syracuse. The shipping cleared in 1905-1906 was 3524 vessels of 3,718,168 tons. Internal communications include a railway about eight miles long from Valletta to Notabile; there are electric tramways and motor omnibus services in several directions. The currency is English. Local weights and measures include the cantar, 175 lb; salm, one imperial quart; caño, 4½ gallons; canna, 6 ft. 10½ in.; the tunno (256 sq. cm.), about a third of an acre.

The principal exports of local produce are potatoes, cumin seed, vegetables, oranges, goats and sheep, cotton goods and stone.

To keep alive, in fair standard of comfort, the population of 206,690, food supplies have to be imported for nine and a half months of the year. The value of exports would be set off against imported food for about one month and a half. The Maltese have to pay for food imports by imperial wages, earned in connexion with naval and military services, by commercial services to passing steamers and visitors, by earnings which emigrants send home from northern Africa and elsewhere, and by interest on investments of Maltese capital abroad. A long absence of the Mediterranean fleet, and withdrawals of imperial forces, produce immediate distress.
